Coverage.py is a tool for measuring code coverage of Python programs. It monitors your program, noting which parts of the code have been executed, then analyzes the source to identify code that could have been executed but was not.

Coverage measurement is typically used to gauge the effectiveness of tests. It can show which parts of your code are being exercised by tests, and which are not.

The latest version is coverage.py 5.3.1, released December 19, 2020. It is supported on:

- Python versions 2.7, 3.5, 3.6, 3.7, 3.8, 3.9, and 3.10 alpha.
- PyPy2 7.3.1 and PyPy3 7.3.1.

FOR ENTERPRISE

Available as part of the [Tidelift Subscription](#). Coverage and thousands of other packages are working with Tidelift to deliver one enterprise subscription that covers all of the open source you use. If you want the flexibility of open source and the confidence of commercial-grade software, this is for you. [Learn more](#).

QUICK START

Getting started is easy:

1. Install coverage.py:

```
$ pip install coverage
```

For more details, see *Installation*.

2. Use `coverage run` to run your test suite and gather data. However you normally run your test suite, you can run your test runner under coverage. If your test runner command starts with “python”, just replace the initial “python” with “coverage run”.

Instructions for specific test runners:

pytest

unittest

nosetest

If you usually use:

```
$ pytest arg1 arg2 arg3
```

then you can run your tests under coverage with:

```
$ coverage run -m pytest arg1 arg2 arg3
```

Many people choose to use the `pytest-cov` plugin, but for most purposes, it is unnecessary.

Change “python” to “coverage run”, so this:

```
$ python -m unittest discover
```

becomes:

```
$ coverage run -m unittest discover
```

Nose has been unmaintained for a long time. You should seriously consider adopting a different test runner.

Change this:

```
$ nosetests arg1 arg2
```

to:

```
$ coverage run -m nose arg1 arg2
```

To limit coverage measurement to code in the current directory, and also find files that weren't executed at all, add the `--source=.` argument to your coverage command line.

3. Use `coverage report` to report on the results:

```
$ coverage report -m
Name                               Stmts  Miss  Cover  Missing
-----
my_program.py                       20     4    80%   33-35, 39
my_other_module.py                   56     6    89%   17-23
-----
TOTAL                                76    10    87%
```

4. For a nicer presentation, use `coverage html` to get annotated HTML listings detailing missed lines:

```
$ coverage html
```

Then open `htmlcov/index.html` in your browser, to see a [report like this](#).

USING COVERAGE.PY

There are a few different ways to use coverage.py. The simplest is the *command line*, which lets you run your program and see the results. If you need more control over how your project is measured, you can use the *API*.

Some test runners provide coverage integration to make it easy to use coverage.py while running tests. For example, `pytest` has the `pytest-cov` plugin.

You can fine-tune coverage.py's view of your code by directing it to ignore parts that you know aren't interesting. See *Specifying source files* and *Excluding code from coverage.py* for details.

GETTING HELP

If the [FAQ](#) doesn't answer your question, you can discuss coverage.py or get help using it on the [Testing In Python mailing list](#).

Bug reports are gladly accepted at the [GitHub issue tracker](#). GitHub also hosts the [code repository](#).

Professional support for coverage.py is available as part of the [Tidelift Subscription](#).

[I can be reached](#) in a number of ways. I'm happy to answer questions about using coverage.py.

MORE INFORMATION

5.1 Installation

You can install coverage.py in the usual ways. The simplest way is with pip:

```
$ pip install coverage
```

5.1.1 C Extension

Coverage.py includes a C extension for speed. It is strongly recommended to use this extension: it is much faster, and is needed to support a number of coverage.py features. Most of the time, the C extension will be installed without any special action on your part.

You can determine if you are using the extension by looking at the output of `coverage --version`:

```
$ coverage --version
Coverage.py, version 5.3.1 with C extension
Documentation at https://coverage.readthedocs.io/en/coverage\unhbox\voidb\x\kern\z@\char`\protect\discretionary{\char\defaultthyphenchar}{}{}5.3.1
```

The first line will either say “with C extension,” or “without C extension.”

If you are missing the extension, first make sure you have the latest version of pip in use when installing coverage.

If you are installing on Linux, you may need to install the python-dev and gcc support files before installing coverage via pip. The exact commands depend on which package manager you use, which Python version you are using, and the names of the packages for your distribution. For example:

```
$ sudo apt-get install python-dev gcc
$ sudo yum install python-devel gcc

$ sudo apt-get install python3-dev gcc
$ sudo yum install python3-devel gcc
```

A few features of coverage.py aren’t supported without the C extension, such as concurrency and plugins.

5.1.2 Checking the installation

If all went well, you should be able to open a command prompt, and see coverage.py installed properly:

```
$ coverage --version
Coverage.py, version 5.3.1 with C extension
Documentation at https://coverage.readthedocs.io/en/coverage\unhbox\voidb@x\
kern\z@\char`\protect\discretionary{\char\defaultthyphenchar}{}}5.3.1
```

You can also invoke coverage.py as a module:

```
$ python -m coverage --version
Coverage.py, version 5.3.1 with C extension
Documentation at https://coverage.readthedocs.io/en/coverage\unhbox\voidb@x\
kern\z@\char`\protect\discretionary{\char\defaultthyphenchar}{}}5.3.1
```

5.2 Command line usage

When you install coverage.py, a command-line script called `coverage` is placed on your path. To help with multi-version installs, it will also create either a `coverage2` or `coverage3` alias, and a `coverage-X.Y` alias, depending on the version of Python you're using. For example, when installing on Python 3.7, you will be able to use `coverage`, `coverage3`, or `coverage-3.7` on the command line.

Coverage.py has a number of commands:

- **run** – *Run a Python program and collect execution data.*
- **combine** – *Combine together a number of data files.*
- **erase** – *Erase previously collected coverage data.*
- **report** – *Report coverage results.*
- **html** – *Produce annotated HTML listings with coverage results.*
- **xml** – *Produce an XML report with coverage results.*
- **json** – *Produce a JSON report with coverage results.*
- **annotate** – *Annotate source files with coverage results.*
- **debug** – *Get diagnostic information.*

Help is available with the **help** command, or with the `--help` switch on any other command:

```
$ coverage help
$ coverage help run
$ coverage run --help
```

Version information for coverage.py can be displayed with `coverage --version`:

```
$ coverage --version
Coverage.py, version 5.3.1 with C extension
Documentation at https://coverage.readthedocs.io/en/coverage\unhbox\voidb@x\
kern\z@\char`\protect\discretionary{\char\defaultthyphenchar}{}}5.3.1
```

Any command can use a configuration file by specifying it with the `--rcfile=FILE` command-line switch. Any option you can set on the command line can also be set in the configuration file. This can be a better way to control coverage.py since the configuration file can be checked into source control, and can provide options that other invocation techniques (like test runner plugins) may not offer. See *Configuration reference* for more details.

5.2.1 Execution: coverage run

You collect execution data by running your Python program with the **run** command:

```
$ coverage run my_program.py arg1 arg2
blah blah ..your program's output.. blah blah
```

Your program runs just as if it had been invoked with the Python command line. Arguments after your file name are passed to your program as usual in `sys.argv`. Rather than providing a file name, you can use the `-m` switch and specify an importable module name instead, just as you can with the Python `-m` switch:

```
$ coverage run -m packagename.modulename arg1 arg2
blah blah ..your program's output.. blah blah
```

Note: In most cases, the program to use here is a test runner, not your program you are trying to measure. The test runner will run your tests and coverage will measure the coverage of your code along the way.

There are many options:

```
$ coverage run --help
Usage: coverage run [options] <pyfile> [program options]

Run a Python program, measuring code execution.

Options:
  -a, --append           Append coverage data to .coverage, otherwise it starts
                        clean each time.
  --branch              Measure branch coverage in addition to statement
                        coverage.
  --concurrency=LIB     Properly measure code using a concurrency library.
                        Valid values are: thread, gevent, greenlet, eventlet,
                        multiprocessing.
  --context=LABEL       The context label to record for this coverage run.
  --include=PAT1,PAT2,...
                        Include only files whose paths match one of these
                        patterns. Accepts shell-style wildcards, which must be
                        quoted.
  -m, --module           <pyfile> is an importable Python module, not a script
                        path, to be run as 'python -m' would run it.
  --omit=PAT1,PAT2,...  Omit files whose paths match one of these patterns.
                        Accepts shell-style wildcards, which must be quoted.
  -L, --pylib           Measure coverage even inside the Python installed
                        library, which isn't done by default.
  -p, --parallel-mode   Append the machine name, process id and random number
                        to the .coverage data file name to simplify collecting
                        data from many processes.
  --source=SRC1,SRC2,...
                        A list of packages or directories of code to be
                        measured.
  --timid              Use a simpler but slower trace method. Try this if you
                        get seemingly impossible results!
  --debug=OPTS         Debug options, separated by commas. [env:
                        COVERAGE_DEBUG]
  -h, --help           Get help on this command.
  --rcfile=RCFILE      Specify configuration file. By default '.coveragerc',
```

(continues on next page)

(continued from previous page)

```
'setup.cfg', 'tox.ini', and 'pyproject.toml' are
tried. [env: COVERAGE_RCFILE]
```

If you want *branch coverage* measurement, use the `--branch` flag. Otherwise only statement coverage is measured.

You can specify the code to measure with the `--source`, `--include`, and `--omit` switches. See *Specifying source files* for details of their interpretation. Remember to put options for run after “run”, but before the program invocation:

```
$ coverage run --source=dir1,dir2 my_program.py arg1 arg2
$ coverage run --source=dir1,dir2 -m packagename.modulename arg1 arg2
```

Coverage.py can measure multi-threaded programs by default. If you are using more exotic concurrency, with the `multiprocessing`, `greenlet`, `eventlet`, or `gevent` libraries, then coverage.py will get very confused. Use the `--concurrency` switch to properly measure programs using these libraries. Give it a value of `multiprocessing`, `thread`, `greenlet`, `eventlet`, or `gevent`. Values other than `thread` require the *C extension*.

If you are using `--concurrency=multiprocessing`, you must set other options in the configuration file. Options on the command line will not be passed to the processes that multiprocessing creates. Best practice is to use the configuration file for all options.

If you are measuring coverage in a multi-process program, or across a number of machines, you’ll want the `--parallel-mode` switch to keep the data separate during measurement. See *Combining data files: coverage combine* below.

You can specify a *static context* for a coverage run with `--context`. This can be any label you want, and will be recorded with the data. See *Measurement contexts* for more information.

By default, coverage.py does not measure code installed with the Python interpreter, for example, the standard library. If you want to measure that code as well as your own, add the `-L` (or `--pylib`) flag.

If your coverage results seem to be overlooking code that you know has been executed, try running coverage.py again with the `--timid` flag. This uses a simpler but slower trace method, and might be needed in rare cases.

Warnings

During execution, coverage.py may warn you about conditions it detects that could affect the measurement process. The possible warnings include:

- `Couldn't parse Python file XXX (couldnt-parse)` During reporting, a file was thought to be Python, but it couldn’t be parsed as Python.
- `Trace function changed, measurement is likely wrong: XXX (trace-changed)`
Coverage measurement depends on a Python setting called the trace function. Other Python code in your product might change that function, which will disrupt coverage.py’s measurement. This warning indicates that has happened. The XXX in the message is the new trace function value, which might provide a clue to the cause.
- `Module XXX has no Python source (module-not-python)` You asked coverage.py to measure module XXX, but once it was imported, it turned out not to have a corresponding .py file. Without a .py file, coverage.py can’t report on missing lines.
- `Module XXX was never imported (module-not-imported)` You asked coverage.py to measure module XXX, but it was never imported by your program.
- `No data was collected (no-data-collected)` Coverage.py ran your program, but didn’t measure any lines as executed. This could be because you asked to measure only modules that never ran, or for other reasons.

- Module XXX was previously imported, but not measured (module-not-measured)
You asked coverage.py to measure module XXX, but it had already been imported when coverage started. This meant coverage.py couldn't monitor its execution.
- Already imported a file that will be measured: XXX (already-imported)
File XXX had already been imported when coverage.py started measurement. Your setting for `--source` or `--include` indicates that you wanted to measure that file. Lines will be missing from the coverage report since the execution during import hadn't been measured.
- `--include` is ignored because `--source` is set (include-ignored) Both
`--include` and `--source` were specified while running code. Both are meant to focus measurement on a particular part of your source code, so `--include` is ignored in favor of `--source`.
- Conflicting dynamic contexts (dynamic-conflict) The `[run] dynamic_context` option is set in the configuration file, but something (probably a test runner plugin) is also calling the `Coverage.switch_context()` function to change the context. Only one of these mechanisms should be in use at a time.

Individual warnings can be disabled with the `disable_warnings` configuration setting. To silence “No data was collected,” add this to your `.coveragerc` file:

```
[run]
disable_warnings = no-data-collected
```

Data file

Coverage.py collects execution data in a file called “.coverage”. If need be, you can set a new file name with the `COVERAGE_FILE` environment variable. This can include a path to another directory.

By default, each run of your program starts with an empty data set. If you need to run your program multiple times to get complete data (for example, because you need to supply different options), you can accumulate data across runs with the `--append` flag on the `run` command.

5.2.2 Combining data files: `coverage combine`

Often test suites are run under different conditions, for example, with different versions of Python, or dependencies, or on different operating systems. In these cases, you can collect coverage data for each test run, and then combine all the separate data files into one combined file for reporting.

The `combine` command reads a number of separate data files, matches the data by source file name, and writes a combined data file with all of the data.

Coverage normally writes data to a file named “.coverage”. The run `--parallel-mode` switch (or `[run] parallel=True` configuration option) tells coverage to expand the file name to include machine name, process id, and a random number so that every data file is distinct:

```
.coverage.Neds-MacBook-Pro.local.88335.316857
.coverage.Geometer.8044.799674
```

You can also define a new data file name with the `[run] data_file` option.

Once you have created a number of these files, you can copy them all to a single directory, and use the `combine` command to combine them into one `.coverage` data file:

```
$ coverage combine
```

You can also name directories or files on the command line:

```
$ coverage combine data1.dat windows_data_files/
```

Coverage.py will collect the data from those places and combine them. The current directory isn't searched if you use command-line arguments. If you also want data from the current directory, name it explicitly on the command line.

When coverage.py combines data files, it looks for files named the same as the data file (defaulting to “.coverage”), with a dotted suffix. Here are some examples of data files that can be combined:

```
.coverage.machine1
.coverage.20120807T212300
.coverage.last_good_run.ok
```

An existing combined data file is ignored and re-written. If you want to use **combine** to accumulate results into the .coverage data file over a number of runs, use the `--append` switch on the **combine** command. This behavior was the default before version 4.2.

To combine data for a source file, coverage has to find its data in each of the data files. Different test runs may run the same source file from different locations. For example, different operating systems will use different paths for the same file, or perhaps each Python version is run from a different subdirectory. Coverage needs to know that different file paths are actually the same source file for reporting purposes.

You can tell coverage.py how different source locations relate with a `[paths]` section in your configuration file (see [\[paths\]](#)). It might be more convenient to use the `[run]` `relative_files` setting to store relative file paths (see [relative_files](#)).

If any of the data files can't be read, coverage.py will print a warning indicating the file and the problem.

```
$ coverage combine --help
Usage: coverage combine [options] <path1> <path2> ... <pathN>

Combine data from multiple coverage files collected with 'run -p'. The
combined results are written to a single file representing the union of the
data. The positional arguments are data files or directories containing data
files. If no paths are provided, data files in the default data file's
directory are combined.

Options:
  -a, --append      Append coverage data to .coverage, otherwise it starts
                    clean each time.
  --debug=OPTS     Debug options, separated by commas. [env: COVERAGE_DEBUG]
  -h, --help        Get help on this command.
  --rcfile=RCFILE  Specify configuration file. By default '.coveragerc',
                    'setup.cfg', 'tox.ini', and 'pyproject.toml' are tried.
                    [env: COVERAGE_RCFILE]
```

5.2.3 Erase data: coverage erase

To erase the collected data, use the **erase** command:

```
$ coverage erase --help
Usage: coverage erase [options]

Erase previously collected coverage data.

Options:
```

(continues on next page)

(continued from previous page)

```

--debug=OPTS      Debug options, separated by commas. [env: COVERAGE_DEBUG]
-h, --help        Get help on this command.
--rcfile=RCFILE   Specify configuration file. By default '.coveragerc',
                  'setup.cfg', 'tox.ini', and 'pyproject.toml' are tried.
                  [env: COVERAGE_RCFILE]

```

If your configuration file indicates parallel data collection, **erase** will remove all of the data files.

5.2.4 Reporting

Coverage.py provides a few styles of reporting, with the **report**, **html**, **annotate**, **json**, and **xml** commands. They share a number of common options.

The command-line arguments are module or file names to report on, if you'd like to report on a subset of the data collected.

The **--include** and **--omit** flags specify lists of file name patterns. They control which files to report on, and are described in more detail in *Specifying source files*.

The **-i** or **--ignore-errors** switch tells coverage.py to ignore problems encountered trying to find source files to report on. This can be useful if some files are missing, or if your Python execution is tricky enough that file names are synthesized without real source files.

If you provide a **--fail-under** value, the total percentage covered will be compared to that value. If it is less, the command will exit with a status code of 2, indicating that the total coverage was less than your target. This can be used as part of a pass/fail condition, for example in a continuous integration server. This option isn't available for **annotate**.

5.2.5 Coverage summary: coverage report

The simplest reporting is a textual summary produced with **report**:

```

$ coverage report
Name                Stmts  Miss  Cover
-----
my_program.py       20     4    80%
my_module.py        15     2    86%
my_other_module.py  56     6    89%
-----
TOTAL                91    12   87%

```

For each module executed, the report shows the count of executable statements, the number of those statements missed, and the resulting coverage, expressed as a percentage.

```

$ coverage report --help
Usage: coverage report [options] [modules]

Report coverage statistics on modules.

Options:
  --contexts=REGEX1,REGEX2,...
                        Only display data from lines covered in the given
                        contexts. Accepts Python regexes, which must be
                        quoted.
  --fail-under=MIN      Exit with a status of 2 if the total coverage is less

```

(continues on next page)

(continued from previous page)

```

than MIN.
-i, --ignore-errors  Ignore errors while reading source files.
--include=PAT1,PAT2,...
                        Include only files whose paths match one of these
                        patterns. Accepts shell-style wildcards, which must be
                        quoted.
--omit=PAT1,PAT2,...  Omit files whose paths match one of these patterns.
                        Accepts shell-style wildcards, which must be quoted.
--precision=N        Number of digits after the decimal point to display
                        for reported coverage percentages.
--sort=COLUMN        Sort the report by the named column: name, stmts,
                        miss, branch, brpart, or cover. Default is name.
-m, --show-missing   Show line numbers of statements in each module that
                        weren't executed.
--skip-covered       Skip files with 100% coverage.
--no-skip-covered    Disable --skip-covered.
--skip-empty        Skip files with no code.
--debug=OPTS        Debug options, separated by commas. [env:
                        COVERAGE_DEBUG]
-h, --help          Get help on this command.
--rcfile=RCFILE     Specify configuration file. By default '.coveragerc',
                        'setup.cfg', 'tox.ini', and 'pyproject.toml' are
                        tried. [env: COVERAGE_RCFILE]

```

The `-m` flag also shows the line numbers of missing statements:

```

$ coverage report -m
Name                               Stmts  Miss  Cover  Missing
-----
my_program.py                       20     4   80%   33-35, 39
my_module.py                         15     2   86%    8, 12
my_other_module.py                   56     6   89%   17-23
-----
TOTAL                               91    12   87%

```

If you are using branch coverage, then branch statistics will be reported in the Branch and BrPart (for Partial Branch) columns, the Missing column will detail the missed branches:

```

$ coverage report -m
Name                               Stmts  Miss  Branch  BrPart  Cover  Missing
-----
my_program.py                       20     4     10     2   80%   33-35, 36->38, 39
my_module.py                         15     2     3     0   86%    8, 12
my_other_module.py                   56     6     5     1   89%   17-23, 40->45
-----
TOTAL                               91    12    18     3   87%

```

You can restrict the report to only certain files by naming them on the command line:

```

$ coverage report -m my_program.py my_other_module.py
Name                               Stmts  Miss  Cover  Missing
-----
my_program.py                       20     4   80%   33-35, 39
my_other_module.py                   56     6   89%   17-23
-----
TOTAL                               76    10   87%

```

The `--skip-covered` switch will skip any file with 100% coverage, letting you focus on the files that still need attention. The `--no-skip-covered` option can be used if needed to see all the files. The `--skip-empty` switch will skip any file with no executable statements.

If you have *recorded contexts*, the `--contexts` option lets you choose which contexts to report on. See *Context reporting* for details.

The `--precision` option controls the number of digits displayed after the decimal point in coverage percentages, defaulting to none.

The `--sort` option is the name of a column to sort the report by.

Other common reporting options are described above in *Reporting*.

5.2.6 HTML annotation: `coverage html`

Coverage.py can annotate your source code for which lines were executed and which were not. The `html` command creates an HTML report similar to the **report** summary, but as an HTML file. Each module name links to the source file decorated to show the status of each line.

Here's a *sample report*.

Lines are highlighted green for executed, red for missing, and gray for excluded. The counts at the top of the file are buttons to turn on and off the highlighting.

A number of keyboard shortcuts are available for navigating the report. Click the keyboard icon in the upper right to see the complete list.

```
$ coverage html --help
Usage: coverage html [options] [modules]

Create an HTML report of the coverage of the files. Each file gets its own
page, with the source decorated to show executed, excluded, and missed lines.

Options:
  --contexts=REGEX1,REGEX2,...
                        Only display data from lines covered in the given
                        contexts. Accepts Python regexes, which must be
                        quoted.
  -d DIR, --directory=DIR
                        Write the output files to DIR.
  --fail-under=MIN      Exit with a status of 2 if the total coverage is less
                        than MIN.
  -i, --ignore-errors  Ignore errors while reading source files.
  --include=PAT1,PAT2,...
                        Include only files whose paths match one of these
                        patterns. Accepts shell-style wildcards, which must be
                        quoted.
  --omit=PAT1,PAT2,...
                        Omit files whose paths match one of these patterns.
                        Accepts shell-style wildcards, which must be quoted.
  --precision=N        Number of digits after the decimal point to display
                        for reported coverage percentages.
  --show-contexts      Show contexts for covered lines.
  --skip-covered       Skip files with 100% coverage.
  --no-skip-covered    Disable --skip-covered.
  --skip-empty         Skip files with no code.
  --title=TITLE        A text string to use as the title on the HTML.
  --debug=OPTS        Debug options, separated by commas. [env:
```

(continues on next page)

(continued from previous page)

```

                                COVERAGE_DEBUG]
-h, --help                    Get help on this command.
--rcfile=RCFILE               Specify configuration file. By default '.coveragerc',
                                'setup.cfg', 'tox.ini', and 'pyproject.toml' are
                                tried. [env: COVERAGE_RCFILE]

```

The title of the report can be set with the `title` setting in the `[html]` section of the configuration file, or the `--title` switch on the command line.

If you prefer a different style for your HTML report, you can provide your own CSS file to apply, by specifying a CSS file in the `[html]` section of the configuration file. See [\[html\]](#) for details.

The `-d` argument specifies an output directory, defaulting to “htmlcov”:

```
$ coverage html -d coverage_html
```

Other common reporting options are described above in [Reporting](#).

Generating the HTML report can be time-consuming. Stored with the HTML report is a data file that is used to speed up reporting the next time. If you generate a new report into the same directory, `coverage.py` will skip generating unchanged pages, making the process faster.

The `--skip-covered` switch will skip any file with 100% coverage, letting you focus on the files that still need attention. The `--skip-empty` switch will skip any file with no executable statements.

The `--precision` option controls the number of digits displayed after the decimal point in coverage percentages, defaulting to none.

If you have [recorded contexts](#), the `--contexts` option lets you choose which contexts to report on, and the `--show-contexts` option will annotate lines with the contexts that ran them. See [Context reporting](#) for details.

5.2.7 XML reporting: `coverage xml`

The `xml` command writes coverage data to a “coverage.xml” file in a format compatible with Cobertura.

```

$ coverage xml --help
Usage: coverage xml [options] [modules]

Generate an XML report of coverage results.

Options:
  --fail-under=MIN           Exit with a status of 2 if the total coverage is less
                              than MIN.
  -i, --ignore-errors       Ignore errors while reading source files.
  --include=PAT1,PAT2,...   Include only files whose paths match one of these
                              patterns. Accepts shell-style wildcards, which must be
                              quoted.
  --omit=PAT1,PAT2,...     Omit files whose paths match one of these patterns.
                              Accepts shell-style wildcards, which must be quoted.
  -o OUTFILE                Write the XML report to this file. Defaults to
                              'coverage.xml'
  --skip-empty              Skip files with no code.
  --debug=OPTS              Debug options, separated by commas. [env:
                              COVERAGE_DEBUG]
  -h, --help                Get help on this command.
  --rcfile=RCFILE           Specify configuration file. By default '.coveragerc',

```

(continues on next page)

(continued from previous page)

```
'setup.cfg', 'tox.ini', and 'pyproject.toml' are
tried. [env: COVERAGE_RCFILE]
```

You can specify the name of the output file with the `-o` switch.

Other common reporting options are described above in *Reporting*.

5.2.8 JSON reporting: `coverage json`

The `json` command writes coverage data to a “coverage.json” file.

```
$ coverage json --help
Usage: coverage json [options] [modules]

Generate a JSON report of coverage results.

Options:
  --contexts=REGEX1,REGEX2,...
                        Only display data from lines covered in the given
                        contexts. Accepts Python regexes, which must be
                        quoted.
  --fail-under=MIN      Exit with a status of 2 if the total coverage is less
                        than MIN.
  -i, --ignore-errors  Ignore errors while reading source files.
  --include=PAT1,PAT2,...
                        Include only files whose paths match one of these
                        patterns. Accepts shell-style wildcards, which must be
                        quoted.
  --omit=PAT1,PAT2,...  Omit files whose paths match one of these patterns.
                        Accepts shell-style wildcards, which must be quoted.
  -o OUTFILE            Write the JSON report to this file. Defaults to
                        'coverage.json'
  --pretty-print        Format the JSON for human readers.
  --show-contexts      Show contexts for covered lines.
  --debug=OPTS         Debug options, separated by commas. [env:
                        COVERAGE_DEBUG]
  -h, --help           Get help on this command.
  --rcfile=RCFILE      Specify configuration file. By default '.coveragerc',
                        'setup.cfg', 'tox.ini', and 'pyproject.toml' are
                        tried. [env: COVERAGE_RCFILE]
```

You can specify the name of the output file with the `-o` switch. The JSON can be nicely formatted by specifying the `--pretty-print` switch.

Other common reporting options are described above in *Reporting*.

5.2.9 Text annotation: coverage annotate

The **annotate** command produces a text annotation of your source code. With a `-d` argument specifying an output directory, each Python file becomes a text file in that directory. Without `-d`, the files are written into the same directories as the original Python files.

Coverage status for each line of source is indicated with a character prefix:

```
> executed
! missing (not executed)
- excluded
```

For example:

```
# A simple function, never called with x==1
> def h(x):
    """Silly function."""
    if 0: #pragma: no cover
        pass
>     if x == 1:
!         a = 1
>     else:
>         a = 2
```

```
$ coverage annotate --help
Usage: coverage annotate [options] [modules]

Make annotated copies of the given files, marking statements that are executed
with > and statements that are missed with !.

Options:
  -d DIR, --directory=DIR          Write the output files to DIR.
  -i, --ignore-errors             Ignore errors while reading source files.
  --include=PAT1,PAT2,...         Include only files whose paths match one of these
                                  patterns. Accepts shell-style wildcards, which must be
                                  quoted.
  --omit=PAT1,PAT2,...           Omit files whose paths match one of these patterns.
                                  Accepts shell-style wildcards, which must be quoted.
  --debug=OPTS                   Debug options, separated by commas. [env:
                                  COVERAGE_DEBUG]
  -h, --help                     Get help on this command.
  --rcfile=RCFILE               Specify configuration file. By default '.coveragerc',
                                  'setup.cfg', 'tox.ini', and 'pyproject.toml' are
                                  tried. [env: COVERAGE_RCFILE]
```

Other common reporting options are described above in [Reporting](#).

5.2.10 Diagnostics: coverage debug

The **debug** command shows internal information to help diagnose problems. If you are reporting a bug about coverage.py, including the output of this command can often help:

```
$ coverage debug sys > please_attach_to_bug_report.txt
```

Three types of information are available:

- **config**: show coverage's configuration
- **sys**: show system configuration
- **data**: show a summary of the collected coverage data
- **premain**: show the call stack invoking coverage

```
$ coverage debug --help
Usage: coverage debug <topic>

Display information about the internals of coverage.py, for diagnosing
problems. Topics are: 'data' to show a summary of the collected data; 'sys' to
show installation information; 'config' to show the configuration; 'premain'
to show what is calling coverage.

Options:
  --debug=OPTS      Debug options, separated by commas. [env: COVERAGE_DEBUG]
  -h, --help        Get help on this command.
  --rcfile=RCFILE   Specify configuration file. By default '.coveragerc',
                    'setup.cfg', 'tox.ini', and 'pyproject.toml' are tried.
                    [env: COVERAGE_RCFILE]
```

--debug

The **--debug** option is also available on all commands. It instructs coverage.py to log internal details of its operation, to help with diagnosing problems. It takes a comma-separated list of options, each indicating a facet of operation to log:

- **callers**: annotate each debug message with a stack trace of the callers to that point.
- **config**: before starting, dump all the *configuration* values.
- **dataio**: log when reading or writing any data file.
- **dataop**: log when data is added to the CoverageData object.
- **multiproc**: log the start and stop of multiprocessing processes.
- **pid**: annotate all warnings and debug output with the process and thread ids.
- **plugin**: print information about plugin operations.
- **process**: show process creation information, and changes in the current directory.
- **self**: annotate each debug message with the object printing the message.
- **sql**: log the SQL statements used for recording data.
- **sys**: before starting, dump all the system and environment information, as with *coverage debug sys*.
- **trace**: print every decision about whether to trace a file or not. For files not being traced, the reason is also given.

Debug options can also be set with the `COVERAGE_DEBUG` environment variable, a comma-separated list of these options.

The debug output goes to `stderr`, unless the `COVERAGE_DEBUG_FILE` environment variable names a different file, which will be appended to.

5.3 Configuration reference

Coverage.py options can be specified in a configuration file. This makes it easier to re-run coverage.py with consistent settings, and also allows for specification of options that are otherwise only available in the *API*.

Configuration files also make it easier to get coverage testing of spawned sub-processes. See *Measuring sub-processes* for more details.

The default name for configuration files is `.coveragerc`, in the same directory coverage.py is being run in. Most of the settings in the configuration file are tied to your source code and how it should be measured, so it should be stored with your source, and checked into source control, rather than put in your home directory.

A different location for the configuration file can be specified with the `--rcfile=FILE` command line option or with the `COVERAGE_RCFILE` environment variable.

Coverage.py will read settings from other usual configuration files if no other configuration file is used. It will automatically read from “`setup.cfg`” or “`tox.ini`” if they exist. In this case, the section names have “`coverage:`” prefixed, so the `[run]` options described below will be found in the `[coverage:run]` section of the file. If coverage.py is installed with the `toml` extra (`pip install coverage[toml]`), it will automatically read from “`pyproject.toml`”. Configuration must be within the `[tool.coverage]` section, for example, `[tool.coverage.run]`.

5.3.1 Syntax

A coverage.py configuration file is in classic `.ini` file format: sections are introduced by a `[section]` header, and contain `name = value` entries. Lines beginning with `#` or `;` are ignored as comments.

Strings don’t need quotes. Multi-valued strings can be created by indenting values on multiple lines.

Boolean values can be specified as `on`, `off`, `true`, `false`, `1`, or `0` and are case-insensitive.

Environment variables can be substituted in by using dollar signs: `$WORD` or `${WORD}` will be replaced with the value of `WORD` in the environment. A dollar sign can be inserted with `$$`. Special forms can be used to control what happens if the variable isn’t defined in the environment:

- If you want to raise an error if an environment variable is undefined, use a question mark suffix: `${WORD?}`.
- If you want to provide a default for missing variables, use a dash with a default value: `${WORD-default value}`.
- Otherwise, missing environment variables will result in empty strings with no error.

Many sections and values correspond roughly to commands and options in the *command-line interface*.

Here’s a sample configuration file:

```
# .coveragerc to control coverage.py
[run]
branch = True

[report]
# Regexes for lines to exclude from consideration
exclude_lines =
```

(continues on next page)

(continued from previous page)

```

# Have to re-enable the standard pragma
pragma: no cover

# Don't complain about missing debug-only code:
def __repr__
if self\.debug

# Don't complain if tests don't hit defensive assertion code:
raise AssertionError
raise NotImplementedError

# Don't complain if non-runnable code isn't run:
if 0:
if __name__ == '__main__':

ignore_errors = True

[html]
directory = coverage_html_report

```

5.3.2 [run]

These values are generally used when running product code, though some apply to more than one command.

`branch` (boolean, default False): whether to measure *branch coverage* in addition to statement coverage.

`command_line` (string): the command-line to run your program. This will be used if you run `coverage run` with no further arguments. Coverage.py options cannot be specified here, other than `-m` to indicate the module to run.

New in version 5.0. `concurrency` (multi-string, default “thread”): the name concurrency libraries in use by the product code. If your program uses `multiprocessing`, `gevent`, `greenlet`, or `eventlet`, you must name that library in this option, or coverage.py will produce very wrong results.

Before version 4.2, this option only accepted a single string.

New in version 4.0. `context` (string): the static context to record for this coverage run. See *Measurement contexts* for more information

New in version 5.0. `cover_pylib` (boolean, default False): whether to measure the Python standard library.

`data_file` (string, default “.coverage”): the name of the data file to use for storing or reporting coverage. This value can include a path to another directory.

`disable_warnings` (multi-string): a list of warnings to disable. Warnings that can be disabled include a short string at the end, the name of the warning. See *Warnings* for specific warnings.

`debug` (multi-string): a list of debug options. See *the run -debug option* for details.

`dynamic_context` (string): the name of a strategy for setting the dynamic context during execution. See *Dynamic contexts* for details.

`include` (multi-string): a list of file name patterns, the files to include in measurement or reporting. Ignored if `source` is set. See *Specifying source files* for details.

`note` (string): this is now obsolete.

`omit` (multi-string): a list of file name patterns, the files to leave out of measurement or reporting. See *Specifying source files* for details.

`parallel` (boolean, default False): append the machine name, process id and random number to the data file name to simplify collecting data from many processes. See *Combining data files: coverage combine* for more information.

`plugins` (multi-string): a list of plugin package names. See *Plug-ins* for more information.

`relative_files` (boolean, default False): *Experimental*: store relative file paths in the data file. This makes it easier to measure code in one (or multiple) environments, and then report in another. See *Combining data files: coverage combine* for details.

New in version 5.0. `source` (multi-string): a list of packages or directories, the source to measure during execution. If set, `include` is ignored. See *Specifying source files* for details.

`source_pkgs` (multi-string): a list of packages, the source to measure during execution. Operates the same as `source`, but only names packages, for resolving ambiguities between packages and directories.

New in version 5.3. `timid` (boolean, default False): use a simpler but slower trace method. This uses PyTracer instead of CTracer, and is only needed in very unusual circumstances. Try this if you get seemingly impossible results.

5.3.3 [paths]

The entries in this section are lists of file paths that should be considered equivalent when combining data from different machines:

```
[paths]
source =
    src/
    /jenkins/build/*/src
    c:\myproj\src
```

The names of the entries (“source” in this example) are ignored, you may choose any name that you like. The value is a list of strings. When combining data with the `combine` command, two file paths will be combined if they start with paths from the same list.

The first value must be an actual file path on the machine where the reporting will happen, so that source code can be found. The other values can be file patterns to match against the paths of collected data, or they can be absolute or relative file paths on the current machine.

In this example, data collected for “/jenkins/build/1234/src/module.py” will be combined with data for “c:\myproj\src\module.py”, and will be reported against the source file found at “src/module.py”.

If you specify more than one list of paths, they will be considered in order. The first list that has a match will be used.

See *Combining data files: coverage combine* for more information.

5.3.4 [report]

Values common to many kinds of reporting.

`exclude_lines` (multi-string): a list of regular expressions. Any line of your source code that matches one of these regexes is excluded from being reported as missing. More details are in *Excluding code from coverage.py*. If you use this option, you are replacing all the exclude regexes, so you’ll need to also supply the “pragma: no cover” regex if you still want to use it.

`fail_under` (float): a target coverage percentage. If the total coverage measurement is under this value, then exit with a status code of 2. If you specify a non-integral value, you must also set `[report] precision` properly to make use of the decimal places. A setting of 100 will fail any value under 100, regardless of the number of decimal places of precision.

`ignore_errors` (boolean, default False): ignore source code that can't be found, emitting a warning instead of an exception.

`include` (multi-string): a list of file name patterns, the files to include in reporting. See *Specifying source files* for details.

`omit` (multi-string): a list of file name patterns, the files to leave out of reporting. See *Specifying source files* for details.

`partial_branches` (multi-string): a list of regular expressions. Any line of code that matches one of these regexes is excused from being reported as a partial branch. More details are in *Branch coverage measurement*. If you use this option, you are replacing all the partial branch regexes so you'll need to also supply the "pragma: no branch" regex if you still want to use it.

`precision` (integer): the number of digits after the decimal point to display for reported coverage percentages. The default is 0, displaying for example "87%". A value of 2 will display percentages like "87.32%". This setting also affects the interpretation of the `fail_under` setting.

`show_missing` (boolean, default False): when running a summary report, show missing lines. See *Coverage summary: coverage report* for more information.

`sort` (string, default "Name"): Sort the text report by the named column. Allowed values are "Name", "Stmts", "Miss", "Branch", "BrPart", or "Cover".

5.3.5 [html]

Values particular to HTML reporting. The values in the `[report]` section also apply to HTML output, where appropriate.

`directory` (string, default "htmlcov"): where to write the HTML report files.

`extra_css` (string): the path to a file of CSS to apply to the HTML report. The file will be copied into the HTML output directory. Don't name it "style.css". This CSS is in addition to the CSS normally used, though you can overwrite as many of the rules as you like.

`show_contexts` (boolean): should the HTML report include an indication on each line of which contexts executed the line. See *Dynamic contexts* for details.

`skip_covered` (boolean, defaulted from `[report] skip_covered`): Don't include files in the report that are 100% covered files. See *Coverage summary: coverage report* for more information.

`skip_empty` (boolean, defaulted from `[report] skip_empty`): Don't include empty files (those that have 0 statements) in the report. See *Coverage summary: coverage report* for more information.

`title` (string, default "Coverage report"): the title to use for the report. Note this is text, not HTML.

5.3.6 [xml]

Values particular to XML reporting. The values in the `[report]` section also apply to XML output, where appropriate.

`output` (string, default "coverage.xml"): where to write the XML report.

`package_depth` (integer, default 99): controls which directories are identified as packages in the report. Directories deeper than this depth are not reported as packages. The default is that all directories are reported as packages.

5.3.7 [json]

Values particular to JSON reporting. The values in the [report] section also apply to JSON output, where appropriate.

New in version 5.0. `output` (string, default “coverage.json”): where to write the JSON file.

`pretty_print` (boolean, default false): controls if the JSON is outputted with whitespace formatted for human consumption (True) or for minimum file size (False).

`show_contexts` (boolean, default false): should the JSON report include an indication of which contexts executed each line. See *Dynamic contexts* for details.

5.4 Specifying source files

When coverage.py is running your program and measuring its execution, it needs to know what code to measure and what code not to. Measurement imposes a speed penalty, and the collected data must be stored in memory and then on disk. More importantly, when reviewing your coverage reports, you don’t want to be distracted with modules that aren’t your concern.

Coverage.py has a number of ways you can focus it in on the code you care about.

5.4.1 Execution

When running your code, the `coverage run` command will by default measure all code, unless it is part of the Python standard library.

You can specify source to measure with the `--source` command-line switch, or the [run] `source` configuration value. The value is a comma- or newline-separated list of directories or package names. If specified, only source inside these directories or packages will be measured. Specifying the source option also enables coverage.py to report on unexecuted files, since it can search the source tree for files that haven’t been measured at all. Only importable files (ones at the root of the tree, or in directories with a `__init__.py` file) will be considered. Files with unusual punctuation in their names will be skipped (they are assumed to be scratch files written by text editors). Files that do not end with `.py` or `.pyo` or `.pyc` will also be skipped.

You can further fine-tune coverage.py’s attention with the `--include` and `--omit` switches (or [run] `include` and [run] `omit` configuration values). `--include` is a list of file name patterns. If specified, only files matching those patterns will be measured. `--omit` is also a list of file name patterns, specifying files not to measure. If both `include` and `omit` are specified, first the set of files is reduced to only those that match the include patterns, then any files that match the omit pattern are removed from the set.

The `include` and `omit` file name patterns follow typical shell syntax: `*` matches any number of characters and `?` matches a single character. Patterns that start with a wildcard character are used as-is, other patterns are interpreted relative to the current directory:

```
[run]
omit =
  # omit anything in a .local directory anywhere
  */.local/*
  # omit everything in /usr
  /usr/*
  # omit this single file
  utils/tirefire.py
```

The source, include, and omit values all work together to determine the source that will be measured.

If both `source` and `include` are set, the `include` value is ignored and a warning is printed on the standard output.

5.4.2 Reporting

Once your program is measured, you can specify the source files you want reported. Usually you want to see all the code that was measured, but if you are measuring a large project, you may want to get reports for just certain parts.

The report commands (`report`, `html`, `json`, `annotate`, and `xml`) all take optional `modules` arguments, and `--include` and `--omit` switches. The `modules` arguments specify particular modules to report on. The `include` and `omit` values are lists of file name patterns, just as with the `run` command.

Remember that the reporting commands can only report on the data that has been collected, so the data you're looking for may not be in the data available for reporting.

Note that these are ways of specifying files to measure. You can also exclude individual source lines. See [Excluding code from coverage.py](#) for details.

5.5 Excluding code from coverage.py

You may have code in your project that you know won't be executed, and you want to tell `coverage.py` to ignore it. For example, you may have debugging-only code that won't be executed during your unit tests. You can tell `coverage.py` to exclude this code during reporting so that it doesn't clutter your reports with noise about code that you don't need to hear about.

Coverage.py will look for comments marking clauses for exclusion. In this code, the "if debug" clause is excluded from reporting:

```
a = my_function1()
if debug: # pragma: no cover
    msg = "blah blah"
    log_message(msg, a)
b = my_function2()
```

Any line with a comment of "pragma: no cover" is excluded. If that line introduces a clause, for example, an if clause, or a function or class definition, then the entire clause is also excluded. Here the `__repr__` function is not reported as missing:

```
class MyObject(object):
    def __init__(self):
        blah1()
        blah2()

    def __repr__(self): # pragma: no cover
        return "<MyObject>"
```

Excluded code is executed as usual, and its execution is recorded in the coverage data as usual. When producing reports though, `coverage.py` excludes it from the list of missing code.

5.5.1 Branch coverage

When measuring *branch coverage*, a conditional will not be counted as a branch if one of its choices is excluded:

```
def only_one_choice(x):
    if x:
        blah1()
        blah2()
    else:          # pragma: no cover
        # x is always true.
        blah3()
```

Because the `else` clause is excluded, the `if` only has one possible next line, so it isn't considered a branch at all.

5.5.2 Advanced exclusion

Coverage.py identifies exclusions by matching lines against a list of regular expressions. Using *configuration files* or the coverage *API*, you can add to that list. This is useful if you have often-used constructs to exclude that can be matched with a regex. You can exclude them all at once without littering your code with exclusion pragmas.

For example, you might decide that `__repr__` functions are usually only used in debugging code, and are uninteresting to test themselves. You could exclude all of them by adding a regex to the exclusion list:

```
[report]
exclude_lines = def __repr__
```

For example, here's a list of exclusions I've used:

```
[report]
exclude_lines =
    pragma: no cover
    def __repr__
    if self.debug:
    if settings.DEBUG
    raise AssertionError
    raise NotImplementedError
    if 0:
    if __name__ == '__main__':
    class .*Protocol\):
```

Note that when using the `exclude_lines` option in a configuration file, you are taking control of the entire list of regexes, so you need to re-specify the default “pragma: no cover” match if you still want it to apply.

A similar pragma, “no branch”, can be used to tailor branch coverage measurement. See *Branch coverage measurement* for details.

5.5.3 Excluding source files

See *Specifying source files* for ways to limit what files coverage.py measures or reports on.

5.6 Branch coverage measurement

In addition to the usual statement coverage, coverage.py also supports branch coverage measurement. Where a line in your program could jump to more than one next line, coverage.py tracks which of those destinations are actually visited, and flags lines that haven't visited all of their possible destinations.

For example:

```

1 def my_partial_fn(x):           # line 1
2     if x:                       #     2
3         y = 10                  #     3
4     return y                   #     4
5
6 my_partial_fn(1)
```

In this code, line 2 is an `if` statement which can go next to either line 3 or line 4. Statement coverage would show all lines of the function as executed. But the `if` was never evaluated as false, so line 2 never jumps to line 4.

Branch coverage will flag this code as not fully covered because of the missing jump from line 2 to line 4. This is known as a partial branch.

5.6.1 How to measure branch coverage

To measure branch coverage, run coverage.py with the `--branch` flag:

```
coverage run --branch myprog.py
```

When you report on the results with `coverage report` or `coverage html`, the percentage of branch possibilities taken will be included in the percentage covered total for each file. The coverage percentage for a file is the actual executions divided by the execution opportunities. Each line in the file is an execution opportunity, as is each branch destination.

The HTML report gives information about which lines had missing branches. Lines that were missing some branches are shown in yellow, with an annotation at the far right showing branch destination line numbers that were not exercised.

The XML and JSON reports produced by `coverage xml` and `coverage json` also include branch information, including separate statement and branch coverage percentages.

5.6.2 How it works

When measuring branches, coverage.py collects pairs of line numbers, a source and destination for each transition from one line to another. Static analysis of the source provides a list of possible transitions. Comparing the measured to the possible indicates missing branches.

The idea of tracking how lines follow each other was from [Titus Brown](#). Thanks, Titus!

5.6.3 Excluding code

If you have *excluded code*, a conditional will not be counted as a branch if one of its choices is excluded:

```
1 def only_one_choice(x):
2     if x:
3         blah1()
4         blah2()
5     else: # pragma: no cover
6         # x is always true.
7         blah3()
```

Because the `else` clause is excluded, the `if` only has one possible next line, so it isn't considered a branch at all.

5.6.4 Structurally partial branches

Sometimes branching constructs are used in unusual ways that don't actually branch. For example:

```
while True:
    if cond:
        break
    do_something()
```

Here the while loop will never exit normally, so it doesn't take both of its "possible" branches. For some of these constructs, such as "while True:" and "if 0:", coverage.py understands what is going on. In these cases, the line will not be marked as a partial branch.

But there are many ways in your own code to write intentionally partial branches, and you don't want coverage.py pestering you about them. You can tell coverage.py that you don't want them flagged by marking them with a pragma:

```
i = 0
while i < 999999999: # pragma: no branch
    if eventually():
        break
```

Here the while loop will never complete because the break will always be taken at some point. Coverage.py can't work that out on its own, but the "no branch" pragma indicates that the branch is known to be partial, and the line is not flagged.

5.7 Measuring sub-processes

Complex test suites may spawn sub-processes to run tests, either to run them in parallel, or because sub-process behavior is an important part of the system under test. Measuring coverage in those sub-processes can be tricky because you have to modify the code spawning the process to invoke coverage.py.

There's an easier way to do it: coverage.py includes a function, `coverage.process_startup()` designed to be invoked when Python starts. It examines the `COVERAGE_PROCESS_START` environment variable, and if it is set, begins coverage measurement. The environment variable's value will be used as the name of the *configuration file* to use.

Note: The subprocess only sees options in the configuration file. Options set on the command line will not be used in the subprocesses.

Note: If you have subprocesses because you are using `multiprocessing`, the `--concurrency=multiprocessing` command-line option should take care of everything for you. See *Execution: coverage run* for details.

When using this technique, be sure to set the `parallel` option to `true` so that multiple `coverage.py` runs will each write their data to a distinct file.

5.7.1 Configuring Python for sub-process coverage

Measuring coverage in sub-processes is a little tricky. When you spawn a sub-process, you are invoking Python to run your program. Usually, to get coverage measurement, you have to use `coverage.py` to run your program. Your sub-process won't be using `coverage.py`, so we have to convince Python to use `coverage.py` even when not explicitly invoked.

To do that, we'll configure Python to run a little `coverage.py` code when it starts. That code will look for an environment variable that tells it to start coverage measurement at the start of the process.

To arrange all this, you have to do two things: set a value for the `COVERAGE_PROCESS_START` environment variable, and then configure Python to invoke `coverage.process_startup()` when Python processes start.

How you set `COVERAGE_PROCESS_START` depends on the details of how you create sub-processes. As long as the environment variable is visible in your sub-process, it will work.

You can configure your Python installation to invoke the `process_startup` function in two ways:

1. Create or append to `sitecustomize.py` to add these lines:

```
import coverage
coverage.process_startup()
```

2. Create a `.pth` file in your Python installation containing:

```
import coverage; coverage.process_startup()
```

The `sitecustomize.py` technique is cleaner, but may involve modifying an existing `sitecustomize.py`, since there can be only one. If there is no `sitecustomize.py` already, you can create it in any directory on the Python path.

The `.pth` technique seems like a hack, but works, and is documented behavior. On the plus side, you can create the file with any name you like so you don't have to coordinate with other `.pth` files. On the minus side, you have to create the file in a system-defined directory, so you may need privileges to write it.

Note that if you use one of these techniques, you must undo them if you uninstall `coverage.py`, since you will be trying to import it during Python start-up. Be sure to remove the change when you uninstall `coverage.py`, or use a more defensive approach to importing it.

5.7.2 Signal handlers and `atexit`

To successfully write a coverage data file, the Python sub-process under analysis must shut down cleanly and have a chance for `coverage.py` to run the `atexit` handler it registers.

For example if you send `SIGTERM` to end the sub-process, but your sub-process has never registered any `SIGTERM` handler, then a coverage file won't be written. See the `atexit` docs for details of when the handler isn't run.

5.8 Measurement contexts

New in version 5.0.

Coverage.py measures whether code was run, but it can also record the context in which it was run. This can provide more information to help you understand the behavior of your tests.

There are two kinds of context: static and dynamic. Static contexts are fixed for an entire run, and are set explicitly with an option. Dynamic contexts change over the course of a single run.

5.8.1 Static contexts

A static context is set by an option when you run coverage.py. The value is fixed for the duration of a run. They can be any text you like, for example, “python3” or “with_numpy”. The context is recorded with the data.

When you *combine multiple data files* together, they can have differing contexts. All of the information is retained, so that the different contexts are correctly recorded in the combined file.

A static context is specified with the `--context=CONTEXT` option to *the coverage run command*, or the `[run] context` setting in the configuration file.

5.8.2 Dynamic contexts

Dynamic contexts are found during execution. They are most commonly used to answer the question “what test ran this line?,” but have been generalized to allow any kind of context tracking. As execution proceeds, the dynamic context changes to record the context of execution. Separate data is recorded for each context, so that it can be analyzed later.

There are three ways to enable dynamic contexts:

- you can set the `[run] dynamic_context` option in your `.coveragerc` file, or
- you can enable a *dynamic context switcher* plugin, or
- another tool (such as a test runner) can call the `Coverage.switch_context()` method to set the context explicitly. The pytest plugin `pytest-cov` has a `--cov-context` option that uses this to set the dynamic context for each test.

The `[run] dynamic_context` setting has only one option now. Set it to `test_function` to start a new dynamic context for every test function:

```
[run]
dynamic_context = test_function
```

Each test function you run will be considered a separate dynamic context, and coverage data will be segregated for each. A test function is any function whose name starts with “test”.

If you have both a static context and a dynamic context, they are joined with a pipe symbol to be recorded as a single string.

Initially, when your program starts running, the dynamic context is an empty string. Any code measured before a dynamic context is set will be recorded in this empty context. For example, if you are recording test names as contexts, then the code run by the test runner before (and between) tests will be in the empty context.

Dynamic contexts can be explicitly disabled by setting `dynamic_context` to `none`.

5.8.3 Context reporting

The `coverage report` and `coverage html` commands both accept `--contexts` option, a comma-separated list of regular expressions. The report will be limited to the contexts that match one of those patterns.

The `coverage html` command also has `--show-contexts`. If set, the HTML report will include an annotation on each covered line indicating the number of contexts that executed the line. Clicking the annotation displays a list of the contexts.

5.8.4 Raw data

For more advanced reporting or analysis, the `.coverage` data file is a SQLite database. See [Coverage.py database schema](#) for details.

5.9 Coverage.py API

There are a few different ways to use `coverage.py` programmatically.

The API to `coverage.py` is in a module called `coverage`. Most of the interface is in the `coverage.Coverage` class. Methods on the `Coverage` object correspond roughly to operations available in the command line interface. For example, a simple use would be:

```
import coverage

cov = coverage.Coverage()
cov.start()

# .. call your code ..

cov.stop()
cov.save()

cov.html_report()
```

`Coverage.py` supports plugins that can change its behavior, to collect information from non-Python files, or to perform complex configuration. See [Plug-in classes](#) for details.

If you want to access the data that `coverage.py` has collected, the `coverage.CoverageData` class provides an API to read `coverage.py` data files.

Note: Only the documented portions of the API are supported. Other names you may find in modules or objects can change their behavior at any time. Please limit yourself to documented methods to avoid problems.

For more intensive data use, you might want to access the `coverage.py` database file directly. The schema is subject to change, so this is for advanced uses only. [Coverage.py database schema](#) explains more.

5.9.1 The Coverage class

```
class coverage.Coverage (data_file=MISSING,      data_suffix=None,      cover_pylib=None,
                        auto_data=False,      timid=None,      branch=None,      config_file=True,
                        source=None,      source_pkgs=None,      omit=None,      include=None,      de-
                        bug=None,      concurrency=None,      check_preimported=False,      con-
                        text=None)
```

Programmatic access to coverage.py.

To use:

```
from coverage import Coverage

cov = Coverage()
cov.start()
#.. call your code ..
cov.stop()
cov.html_report(directory='covhtml')
```

Note: in keeping with Python custom, names starting with underscore are not part of the public API. They might stop working at any point. Please limit yourself to documented methods to avoid problems.

```
__init__ (data_file=MISSING, data_suffix=None, cover_pylib=None, auto_data=False, timid=None,
          branch=None, config_file=True, source=None, source_pkgs=None, omit=None, in-
          clude=None, debug=None, concurrency=None, check_preimported=False, context=None)
```

Many of these arguments duplicate and override values that can be provided in a configuration file. Parameters that are missing here will use values from the config file.

data_file is the base name of the data file to use. The config value defaults to “.coverage”. None can be provided to prevent writing a data file. *data_suffix* is appended (with a dot) to *data_file* to create the final file name. If *data_suffix* is simply True, then a suffix is created with the machine and process identity included.

cover_pylib is a boolean determining whether Python code installed with the Python interpreter is measured. This includes the Python standard library and any packages installed with the interpreter.

If *auto_data* is true, then any existing data file will be read when coverage measurement starts, and data will be saved automatically when measurement stops.

If *timid* is true, then a slower and simpler trace function will be used. This is important for some environments where manipulation of tracing functions breaks the faster trace function.

If *branch* is true, then branch coverage will be measured in addition to the usual statement coverage.

config_file determines what configuration file to read:

- If it is “.coveragerc”, it is interpreted as if it were True, for backward compatibility.
- If it is a string, it is the name of the file to read. If the file can’t be read, it is an error.
- If it is True, then a few standard files names are tried (“.coveragerc”, “setup.cfg”, “tox.ini”). It is not an error for these files to not be found.
- If it is False, then no configuration file is read.

source is a list of file paths or package names. Only code located in the trees indicated by the file paths or package names will be measured.

source_pkgs is a list of package names. It works the same as *source*, but can be used to name packages where the name can also be interpreted as a file path.

include and *omit* are lists of file name patterns. Files that match *include* will be measured, files that match *omit* will not. Each will also accept a single string argument.

debug is a list of strings indicating what debugging information is desired.

concurrency is a string indicating the concurrency library being used in the measured code. Without this, coverage.py will get incorrect results if these libraries are in use. Valid strings are “greenlet”, “eventlet”, “gevent”, “multiprocessing”, or “thread” (the default). This can also be a list of these strings.

If *check_preimported* is true, then when coverage is started, the already-imported files will be checked to see if they should be measured by coverage. Importing measured files before coverage is started can mean that code is missed.

context is a string to use as the *static context* label for collected data.

New in version 4.0: The *concurrency* parameter.

New in version 4.2: The *concurrency* parameter can now be a list of strings.

New in version 5.0: The *check_preimported* and *context* parameters.

New in version 5.3: The *source_pkgs* parameter.

analysis (*morf*)

Like *analysis2* but doesn't return excluded line numbers.

analysis2 (*morf*)

Analyze a module.

morf is a module or a file name. It will be analyzed to determine its coverage statistics. The return value is a 5-tuple:

- The file name for the module.
- A list of line numbers of executable statements.
- A list of line numbers of excluded statements.
- A list of line numbers of statements not run (missing from execution).
- A readable formatted string of the missing line numbers.

The analysis uses the source file itself and the current measured coverage data.

annotate (*morfs=None, directory=None, ignore_errors=None, omit=None, include=None, contexts=None*)

Annotate a list of modules.

Each module in *morfs* is annotated. The source is written to a new file, named with a “cover” suffix, with each line prefixed with a marker to indicate the coverage of the line. Covered lines have “>”, excluded lines have “-“, and missing lines have “!”.

See *report ()* for other arguments.

clear_exclude (*which='exclude'*)

Clear the exclude list.

combine (*data_paths=None, strict=False*)

Combine together a number of similarly-named coverage data files.

All coverage data files whose name starts with *data_file* (from the *coverage()* constructor) will be read, and combined together into the current measurements.

data_paths is a list of files or directories from which data should be combined. If no list is passed, then the data files from the directory indicated by the current data file (probably the current directory) will be combined.

If *strict* is true, then it is an error to attempt to combine when there are no data files to combine.

New in version 4.0: The *data_paths* parameter.

New in version 4.3: The *strict* parameter.

classmethod current ()

Get the latest started *Coverage* instance, if any.

Returns: a *Coverage* instance, or None.

New in version 5.0.

erase ()

Erase previously collected coverage data.

This removes the in-memory data collected in this session as well as discarding the data file.

exclude (*regex*, *which*='exclude')

Exclude source lines from execution consideration.

A number of lists of regular expressions are maintained. Each list selects lines that are treated differently during reporting.

which determines which list is modified. The “exclude” list selects lines that are not considered executable at all. The “partial” list indicates lines with branches that are not taken.

regex is a regular expression. The regex is added to the specified list. If any of the regexes in the list is found in a line, the line is marked for special treatment during reporting.

get_data ()

Get the collected data.

Also warn about various problems collecting data.

Returns a *coverage.CoverageData*, the collected coverage data.

New in version 4.0.

get_exclude_list (*which*='exclude')

Return a list of excluded regex patterns.

which indicates which list is desired. See *exclude()* for the lists that are available, and their meaning.

get_option (*option_name*)

Get an option from the configuration.

option_name is a colon-separated string indicating the section and option name. For example, the branch option in the [run] section of the config file would be indicated with “run:branch”.

Returns the value of the option. The type depends on the option selected.

As a special case, an *option_name* of "paths" will return an OrderedDict with the entire [paths] section value.

New in version 4.0.

html_report (*morfs*=None, *directory*=None, *ignore_errors*=None, *omit*=None, *include*=None, *extra_css*=None, *title*=None, *skip_covered*=None, *show_contexts*=None, *contexts*=None, *skip_empty*=None, *precision*=None)

Generate an HTML report.

The HTML is written to *directory*. The file “index.html” is the overview starting point, with links to more detailed pages for individual modules.

extra_css is a path to a file of other CSS to apply on the page. It will be copied into the HTML directory.

title is a text string (not HTML) to use as the title of the HTML report.

See *report()* for other arguments.

Returns a float, the total percentage covered.

Note: The HTML report files are generated incrementally based on the source files and coverage results. If you modify the report files, the changes will not be considered. You should be careful about changing the files in the report folder.

json_report (*morfs=None, outfile=None, ignore_errors=None, omit=None, include=None, contexts=None, pretty_print=None, show_contexts=None*)

Generate a JSON report of coverage results.

Each module in *morfs* is included in the report. *outfile* is the path to write the file to, “-” will write to stdout.

See *report()* for other arguments.

Returns a float, the total percentage covered.

New in version 5.0.

load()

Load previously-collected coverage data from the data file.

report (*morfs=None, show_missing=None, ignore_errors=None, file=None, omit=None, include=None, skip_covered=None, contexts=None, skip_empty=None, precision=None, sort=None*)

Write a textual summary report to *file*.

Each module in *morfs* is listed, with counts of statements, executed statements, missing statements, and a list of lines missed.

If *show_missing* is true, then details of which lines or branches are missing will be included in the report. If *ignore_errors* is true, then a failure while reporting a single file will not stop the entire report.

file is a file-like object, suitable for writing.

include is a list of file name patterns. Files that match will be included in the report. Files matching *omit* will not be included in the report.

If *skip_covered* is true, don’t report on files with 100% coverage.

If *skip_empty* is true, don’t report on empty files (those that have no statements).

contexts is a list of regular expressions. Only data from *dynamic contexts* that match one of those expressions (using *re.search*) will be included in the report.

precision is the number of digits to display after the decimal point for percentages.

All of the arguments default to the settings read from the *configuration file*.

Returns a float, the total percentage covered.

New in version 4.0: The *skip_covered* parameter.

New in version 5.0: The *contexts* and *skip_empty* parameters.

New in version 5.2: The *precision* parameter.

save()

Save the collected coverage data to the data file.

set_option (*option_name, value*)

Set an option in the configuration.

option_name is a colon-separated string indicating the section and option name. For example, the `branch` option in the `[run]` section of the config file would be indicated with `"run:branch"`.

value is the new value for the option. This should be an appropriate Python value. For example, use `True` for booleans, not the string `"True"`.

As an example, calling:

```
cov.set_option("run:branch", True)
```

has the same effect as this configuration file:

```
[run]
branch = True
```

As a special case, an *option_name* of `"paths"` will replace the entire `[paths]` section. The value should be an `OrderedDict`.

New in version 4.0.

start ()

Start measuring code coverage.

Coverage measurement only occurs in functions called after `start ()` is invoked. Statements in the same scope as `start ()` won't be measured.

Once you invoke `start ()`, you must also call `stop ()` eventually, or your process might not shut down cleanly.

stop ()

Stop measuring code coverage.

switch_context (new_context)

Switch to a new dynamic context.

new_context is a string to use as the *dynamic context* label for collected data. If a *static context* is in use, the static and dynamic context labels will be joined together with a pipe character.

Coverage collection must be started already.

New in version 5.0.

xml_report (morfs=None, outfile=None, ignore_errors=None, omit=None, include=None, contexts=None, skip_empty=None)

Generate an XML report of coverage results.

The report is compatible with Cobertura reports.

Each module in *morfs* is included in the report. *outfile* is the path to write the file to, `"-"` will write to stdout.

See `report ()` for other arguments.

Returns a float, the total percentage covered.

5.9.2 coverage module

The most important thing in the coverage module is the `coverage.Coverage` class, described in *The Coverage class*, but there are a few other things also.

`coverage.version_info`

A tuple of five elements, similar to `sys.version_info`: *major*, *minor*, *micro*, *releaselevel*, and *serial*. All values except *releaselevel* are integers; the release level is 'alpha', 'beta', 'candidate', or 'final'. Unlike `sys.version_info`, the elements are not available by name.

`coverage.__version__`

A string with the version of coverage.py, for example, "5.0b2".

class `coverage.CoverageException`

An exception raised by a coverage.py function.

Starting coverage.py automatically

This function is used to start coverage measurement automatically when Python starts. See *Measuring sub-processes* for details.

`coverage.process_startup()`

Call this at Python start-up to perhaps measure coverage.

If the environment variable `COVERAGE_PROCESS_START` is defined, coverage measurement is started. The value of the variable is the config file to use.

There are two ways to configure your Python installation to invoke this function when Python starts:

1. Create or append to `sitecustomize.py` to add these lines:

```
import coverage
coverage.process_startup()
```

2. Create a `.pth` file in your Python installation containing:

```
import coverage; coverage.process_startup()
```

Returns the `Coverage` instance that was started, or `None` if it was not started by this call.

5.9.3 Plug-in classes

New in version 4.0.

Plug-in interfaces for coverage.py.

Coverage.py supports a few different kinds of plug-ins that change its behavior:

- File tracers implement tracing of non-Python file types.
- Configurers add custom configuration, using Python code to change the configuration.
- Dynamic context switchers decide when the dynamic context has changed, for example, to record what test function produced the coverage.

To write a coverage.py plug-in, create a module with a subclass of `CoveragePlugin`. You will override methods in your class to participate in various aspects of coverage.py's processing. Different types of plug-ins have to override different methods.

Any plug-in can optionally implement `sys_info()` to provide debugging information about their operation.

Your module must also contain a `coverage_init` function that registers an instance of your plug-in class:

```
import coverage

class MyPlugin(coverage.CoveragePlugin):
    ...

def coverage_init(reg, options):
    reg.add_file_tracer(MyPlugin())
```

You use the `reg` parameter passed to your `coverage_init` function to register your plug-in object. The registration method you call depends on what kind of plug-in it is.

If your plug-in takes options, the `options` parameter is a dictionary of your plug-in's options from the `coverage.py` configuration file. Use them however you want to configure your object before registering it.

Coverage.py will store its own information on your plug-in object, using attributes whose names start with `_coverage_`. Don't be startled.

Warning: Plug-ins are imported by `coverage.py` before it begins measuring code. If you write a plugin in your own project, it might import your product code before `coverage.py` can start measuring. This can result in your own code being reported as missing.

One solution is to put your plugins in your project tree, but not in your importable Python package.

File Tracers

File tracers implement measurement support for non-Python files. File tracers implement the `file_tracer()` method to claim files and the `file_reporter()` method to report on those files.

In your `coverage_init` function, use the `add_file_tracer` method to register your file tracer.

Configurers

New in version 4.5.

Configurers modify the configuration of `coverage.py` during start-up. Configurers implement the `configure()` method to change the configuration.

In your `coverage_init` function, use the `add_configurer` method to register your configurer.

Dynamic Context Switchers

New in version 5.0.

Dynamic context switcher plugins implement the `dynamic_context()` method to dynamically compute the context label for each measured frame.

Computed context labels are useful when you want to group measured data without modifying the source code.

For example, you could write a plugin that checks `frame.f_code` to inspect the currently executed method, and set the context label to a fully qualified method name if it's an instance method of `unittest.TestCase` and the method name starts with 'test'. Such a plugin would provide basic coverage grouping by test and could be used with test runners that have no built-in coverage support.

In your `coverage_init` function, use the `add_dynamic_context` method to register your dynamic context switcher.

The CoveragePlugin class

class `coverage.CoveragePlugin`

Base class for coverage.py plug-ins.

file_tracer (*filename*)

Get a *FileTracer* object for a file.

Plug-in type: file tracer.

Every Python source file is offered to your plug-in to give it a chance to take responsibility for tracing the file. If your plug-in can handle the file, it should return a *FileTracer* object. Otherwise return `None`.

There is no way to register your plug-in for particular files. Instead, this method is invoked for all files as they are executed, and the plug-in decides whether it can trace the file or not. Be prepared for *filename* to refer to all kinds of files that have nothing to do with your plug-in.

The file name will be a Python file being executed. There are two broad categories of behavior for a plug-in, depending on the kind of files your plug-in supports:

- Static file names: each of your original source files has been converted into a distinct Python file. Your plug-in is invoked with the Python file name, and it maps it back to its original source file.
- Dynamic file names: all of your source files are executed by the same Python file. In this case, your plug-in implements *FileTracer.dynamic_source_filename()* to provide the actual source file for each execution frame.

filename is a string, the path to the file being considered. This is the absolute real path to the file. If you are comparing to other paths, be sure to take this into account.

Returns a *FileTracer* object to use to trace *filename*, or `None` if this plug-in cannot trace this file.

file_reporter (*filename*)

Get the *FileReporter* class to use for a file.

Plug-in type: file tracer.

This will only be invoked if *filename* returns non-`None` from *file_tracer()*. It's an error to return `None` from this method.

Returns a *FileReporter* object to use to report on *filename*, or the string "python" to have coverage.py treat the file as Python.

dynamic_context (*frame*)

Get the dynamically computed context label for *frame*.

Plug-in type: dynamic context.

This method is invoked for each frame when outside of a dynamic context, to see if a new dynamic context should be started. If it returns a string, a new context label is set for this and deeper frames. The dynamic context ends when this frame returns.

Returns a string to start a new dynamic context, or `None` if no new context should be started.

find_executable_files (*src_dir*)

Yield all of the executable files in *src_dir*, recursively.

Plug-in type: file tracer.

Executability is a plug-in-specific property, but generally means files which would have been considered for coverage analysis, had they been included automatically.

Returns or yields a sequence of strings, the paths to files that could have been executed, including files that had been executed.

configure (*config*)

Modify the configuration of coverage.py.

Plug-in type: configurer.

This method is called during coverage.py start-up, to give your plug-in a chance to change the configuration. The *config* parameter is an object with *get_option()* and *set_option()* methods. Do not call any other methods on the *config* object.

sys_info ()

Get a list of information useful for debugging.

Plug-in type: any.

This method will be invoked for `--debug=sys`. Your plug-in can return any information it wants to be displayed.

Returns a list of pairs: [(*name*, *value*), ...].

The FileTracer class

class coverage.FileTracer

Support needed for files during the execution phase.

File tracer plug-ins implement subclasses of FileTracer to return from their *file_tracer()* method.

You may construct this object from *CoveragePlugin.file_tracer()* any way you like. A natural choice would be to pass the file name given to *file_tracer*.

FileTracer objects should only be created in the *CoveragePlugin.file_tracer()* method.

See *How coverage.py works* for details of the different coverage.py phases.

source_filename ()

The source file name for this file.

This may be any file name you like. A key responsibility of a plug-in is to own the mapping from Python execution back to whatever source file name was originally the source of the code.

See *CoveragePlugin.file_tracer()* for details about static and dynamic file names.

Returns the file name to credit with this execution.

has_dynamic_source_filename ()

Does this FileTracer have dynamic source file names?

FileTracers can provide dynamically determined file names by implementing *dynamic_source_filename()*. Invoking that function is expensive. To determine whether to invoke it, coverage.py uses the result of this function to know if it needs to bother invoking *dynamic_source_filename()*.

See *CoveragePlugin.file_tracer()* for details about static and dynamic file names.

Returns True if *dynamic_source_filename()* should be called to get dynamic source file names.

dynamic_source_filename (*filename*, *frame*)

Get a dynamically computed source file name.

Some plug-ins need to compute the source file name dynamically for each frame.

This function will not be invoked if `has_dynamic_source_filename()` returns False.

Returns the source file name for this frame, or None if this frame shouldn't be measured.

line_number_range (*frame*)

Get the range of source line numbers for a given a call frame.

The call frame is examined, and the source line number in the original file is returned. The return value is a pair of numbers, the starting line number and the ending line number, both inclusive. For example, returning (5, 7) means that lines 5, 6, and 7 should be considered executed.

This function might decide that the frame doesn't indicate any lines from the source file were executed. Return (-1, -1) in this case to tell coverage.py that no lines should be recorded for this frame.

The FileReporter class

class coverage.**FileReporter** (*filename*)

Support needed for files during the analysis and reporting phases.

File tracer plug-ins implement a subclass of *FileReporter*, and return instances from their *CoveragePlugin.file_reporter()* method.

There are many methods here, but only *lines()* is required, to provide the set of executable lines in the file.

See *How coverage.py works* for details of the different coverage.py phases.

relative_filename ()

Get the relative file name for this file.

This file path will be displayed in reports. The default implementation will supply the actual project-relative file path. You only need to supply this method if you have an unusual syntax for file paths.

source ()

Get the source for the file.

Returns a Unicode string.

The base implementation simply reads the *self.filename* file and decodes it as UTF8. Override this method if your file isn't readable as a text file, or if you need other encoding support.

lines ()

Get the executable lines in this file.

Your plug-in must determine which lines in the file were possibly executable. This method returns a set of those line numbers.

Returns a set of line numbers.

excluded_lines ()

Get the excluded executable lines in this file.

Your plug-in can use any method it likes to allow the user to exclude executable lines from consideration.

Returns a set of line numbers.

The base implementation returns the empty set.

translate_lines (*lines*)

Translate recorded lines into reported lines.

Some file formats will want to report lines slightly differently than they are recorded. For example, Python records the last line of a multi-line statement, but reports are nicer if they mention the first line.

Your plug-in can optionally define this method to perform these kinds of adjustment.

lines is a sequence of integers, the recorded line numbers.

Returns a set of integers, the adjusted line numbers.

The base implementation returns the numbers unchanged.

arcs ()

Get the executable arcs in this file.

To support branch coverage, your plug-in needs to be able to indicate possible execution paths, as a set of line number pairs. Each pair is a (*prev*, *next*) pair indicating that execution can transition from the *prev* line number to the *next* line number.

Returns a set of pairs of line numbers. The default implementation returns an empty set.

no_branch_lines ()

Get the lines excused from branch coverage in this file.

Your plug-in can use any method it likes to allow the user to exclude lines from consideration of branch coverage.

Returns a set of line numbers.

The base implementation returns the empty set.

translate_arcs (*arcs*)

Translate recorded arcs into reported arcs.

Similar to *translate_lines* (), but for arcs. *arcs* is a set of line number pairs.

Returns a set of line number pairs.

The default implementation returns *arcs* unchanged.

exit_counts ()

Get a count of exits from that each line.

To determine which lines are branches, coverage.py looks for lines that have more than one exit. This function creates a dict mapping each executable line number to a count of how many exits it has.

To be honest, this feels wrong, and should be refactored. Let me know if you attempt to implement this method in your plug-in. . .

missing_arc_description (*start*, *end*, *executed_arcs*=None)

Provide an English sentence describing a missing arc.

The *start* and *end* arguments are the line numbers of the missing arc. Negative numbers indicate entering or exiting code objects.

The *executed_arcs* argument is a set of line number pairs, the arcs that were executed in this file.

By default, this simply returns the string “Line {start} didn’t jump to {end}”.

source_token_lines ()

Generate a series of tokenized lines, one for each line in *source*.

These tokens are used for syntax-colored reports.

Each line is a list of pairs, each pair is a token:

```
[('key', 'def'), ('ws', ' '), ('nam', 'hello'), ('op', '('), ... ]
```

Each pair has a token class, and the token text. The token classes are:

- 'com': a comment

- 'key': a keyword
- 'nam': a name, or identifier
- 'num': a number
- 'op': an operator
- 'str': a string literal
- 'ws': some white space
- 'txt': some other kind of text

If you concatenate all the token texts, and then join them with newlines, you should have your original source back.

The default implementation simply returns each line tagged as 'txt'.

5.9.4 The CoverageData class

New in version 4.0.

class coverage.CoverageData (*basename=None, suffix=None, no_disk=False, warn=None, debug=None*)

Manages collected coverage data, including file storage.

This class is the public supported API to the data that coverage.py collects during program execution. It includes information about what code was executed. It does not include information from the analysis phase, to determine what lines could have been executed, or what lines were not executed.

Note: The data file is currently a SQLite database file, with a *documented schema*. The schema is subject to change though, so be careful about querying it directly. Use this API if you can to isolate yourself from changes.

There are a number of kinds of data that can be collected:

- **lines:** the line numbers of source lines that were executed. These are always available.
- **arcs:** pairs of source and destination line numbers for transitions between source lines. These are only available if branch coverage was used.
- **file tracer names:** the module names of the file tracer plugins that handled each file in the data.

Lines, arcs, and file tracer names are stored for each source file. File names in this API are case-sensitive, even on platforms with case-insensitive file systems.

A data file either stores lines, or arcs, but not both.

A data file is associated with the data when the *CoverageData* is created, using the parameters *basename*, *suffix*, and *no_disk*. The base name can be queried with *base_filename()*, and the actual file name being used is available from *data_filename()*.

To read an existing coverage.py data file, use *read()*. You can then access the line, arc, or file tracer data with *lines()*, *arcs()*, or *file_tracer()*.

The *has_arcs()* method indicates whether arc data is available. You can get a set of the files in the data with *measured_files()*. As with most Python containers, you can determine if there is any data at all by using this object as a boolean value.

The contexts for each line in a file can be read with *contexts_by_lineno()*.

To limit querying to certain contexts, use `set_query_context()` or `set_query_contexts()`. These will narrow the focus of subsequent `lines()`, `arcs()`, and `contexts_by_lineno()` calls. The set of all measured context names can be retrieved with `measured_contexts()`.

Most data files will be created by coverage.py itself, but you can use methods here to create data files if you like. The `add_lines()`, `add_arcs()`, and `add_file_tracers()` methods add data, in ways that are convenient for coverage.py.

To record data for contexts, use `set_context()` to set a context to be used for subsequent `add_lines()` and `add_arcs()` calls.

To add a source file without any measured data, use `touch_file()`, or `touch_files()` for a list of such files.

Write the data to its file with `write()`.

You can clear the data in memory with `erase()`. Two data collections can be combined by using `update()` on one `CoverageData`, passing it the other.

Data in a `CoverageData` can be serialized and deserialized with `dumps()` and `loads()`.

`__init__` (*basename=None, suffix=None, no_disk=False, warn=None, debug=None*)

Create a `CoverageData` object to hold coverage-measured data.

Parameters

- **basename** (*str*) – the base name of the data file, defaulting to “.coverage”.
- **suffix** (*str or bool*) – has the same meaning as the `data_suffix` argument to `coverage.Coverage`.
- **no_disk** (*bool*) – if True, keep all data in memory, and don’t write any disk file.
- **warn** – a warning callback function, accepting a warning message argument.
- **debug** – a `DebugControl` object (optional)

add_arcs (*arc_data*)

Add measured arc data.

arc_data is a dictionary mapping file names to dictionaries:

```
{ filename: { (l1,l2): None, ... }, ... }
```

add_file_tracers (*file_tracers*)

Add per-file plugin information.

file_tracers is { filename: plugin_name, ... }

add_lines (*line_data*)

Add measured line data.

line_data is a dictionary mapping file names to dictionaries:

```
{ filename: { lineno: None, ... }, ... }
```

arcs (*filename*)

Get the list of arcs executed for a file.

If the file was not measured, returns None. A file might be measured, and have no arcs executed, in which case an empty list is returned.

If the file was executed, returns a list of 2-tuples of integers. Each pair is a starting line number and an ending line number for a transition from one line to another. The list is in no particular order.

Negative numbers have special meaning. If the starting line number is `-N`, it represents an entry to the code object that starts at line `N`. If the ending line number is `-N`, it's an exit from the code object that starts at line `N`.

base_filename ()

The base filename for storing data.

New in version 5.0.

contexts_by_lineno (*filename*)

Get the contexts for each line in a file.

Returns A dict mapping line numbers to a list of context names.

New in version 5.0.

data_filename ()

Where is the data stored?

New in version 5.0.

dumps ()

Serialize the current data to a byte string.

The format of the serialized data is not documented. It is only suitable for use with `loads()` in the same version of coverage.py.

Returns A byte string of serialized data.

New in version 5.0.

erase (*parallel=False*)

Erase the data in this object.

If *parallel* is true, then also deletes data files created from the basename by parallel-mode.

file_tracer (*filename*)

Get the plugin name of the file tracer for a file.

Returns the name of the plugin that handles this file. If the file was measured, but didn't use a plugin, then "" is returned. If the file was not measured, then None is returned.

has_arcs ()

Does the database have arcs (True) or lines (False).

lines (*filename*)

Get the list of lines executed for a file.

If the file was not measured, returns None. A file might be measured, and have no lines executed, in which case an empty list is returned.

If the file was executed, returns a list of integers, the line numbers executed in the file. The list is in no particular order.

loads (*data*)

Deserialize data from `dumps()`

Use with a newly-created empty `CoverageData` object. It's undefined what happens if the object already has data in it.

Parameters *data* – A byte string of serialized data produced by `dumps()`.

New in version 5.0.

measured_contexts ()

A set of all contexts that have been measured.

New in version 5.0.

measured_files ()

A set of all files that had been measured.

read ()

Start using an existing data file.

set_context (context)

Set the current context for future *add_lines ()* etc.

context is a str, the name of the context to use for the next data additions. The context persists until the next *set_context ()*.

New in version 5.0.

set_query_context (context)

Set a context for subsequent querying.

The next *lines ()*, *arcs ()*, or *contexts_by_lineno ()* calls will be limited to only one context. *context* is a string which must match a context exactly. If it does not, no exception is raised, but queries will return no data.

New in version 5.0.

set_query_contexts (contexts)

Set a number of contexts for subsequent querying.

The next *lines ()*, *arcs ()*, or *contexts_by_lineno ()* calls will be limited to the specified contexts. *contexts* is a list of Python regular expressions. Contexts will be matched using *re.search*. Data will be included in query results if they are part of any of the contexts matched.

New in version 5.0.

classmethod sys_info ()

Our information for *Coverage.sys_info*.

Returns a list of (key, value) pairs.

touch_file (filename, plugin_name="")

Ensure that *filename* appears in the data, empty if needed.

plugin_name is the name of the plugin responsible for this file. It is used to associate the right filereporter, etc.

touch_files (filenames, plugin_name="")

Ensure that *filenames* appear in the data, empty if needed.

plugin_name is the name of the plugin responsible for these files. It is used to associate the right filereporter, etc.

update (other_data, aliases=None)

Update this data with data from several other *CoverageData* instances.

If *aliases* is provided, it's a *PathAliases* object that is used to re-map paths to match the local machine's.

write ()

Ensure the data is written to the data file.

5.9.5 Coverage.py database schema

New in version 5.0.

Coverage.py stores data in a SQLite database, by default called `.coverage`. For most needs, the `CoverageData` API will be sufficient, and should be preferred to accessing the database directly. Only advanced uses will need to use the database.

The schema can change without changing the major version of coverage.py, so be careful when accessing the database directly. The `coverage_schema` table has the schema number of the database. The schema described here corresponds to:

```
SCHEMA_VERSION = 7
```

You can use SQLite tools such as the `sqlite3` module in the Python standard library to access the data. Some data is stored in a packed format that will need custom functions to access. See `register_sqlite_functions()`.

Database schema

This is the database schema.

TODO: explain more. Readers: what needs explaining?

```
CREATE TABLE coverage_schema (
    -- One row, to record the version of the schema in this db.
    version integer
);

CREATE TABLE meta (
    -- Key-value pairs, to record metadata about the data
    key text,
    value text,
    unique (key)
    -- Keys:
    -- 'has_arcs' boolean      -- Is this data recording branches?
    -- 'sys_argv' text        -- The coverage command line that recorded the data.
    -- 'version' text         -- The version of coverage.py that made the file.
    -- 'when' text           -- Datetime when the file was created.
);

CREATE TABLE file (
    -- A row per file measured.
    id integer primary key,
    path text,
    unique (path)
);

CREATE TABLE context (
    -- A row per context measured.
    id integer primary key,
    context text,
    unique (context)
);

CREATE TABLE line_bits (
    -- If recording lines, a row per context per file executed.
    -- All of the line numbers for that file/context are in one numbits.
```

(continues on next page)

(continued from previous page)

```

file_id integer,          -- foreign key to `file`.
context_id integer,      -- foreign key to `context`.
numbits blob,           -- see the numbits functions in coverage.numbits
foreign key (file_id) references file (id),
foreign key (context_id) references context (id),
unique (file_id, context_id)
);

CREATE TABLE arc (
  -- If recording branches, a row per context per from/to line transition executed.
  file_id integer,        -- foreign key to `file`.
  context_id integer,     -- foreign key to `context`.
  fromno integer,         -- line number jumped from.
  tono integer,           -- line number jumped to.
  foreign key (file_id) references file (id),
  foreign key (context_id) references context (id),
  unique (file_id, context_id, fromno, tono)
);

CREATE TABLE tracer (
  -- A row per file indicating the tracer used for that file.
  file_id integer primary key,
  tracer text,
  foreign key (file_id) references file (id)
);

```

Numbits

Functions to manipulate packed binary representations of number sets.

To save space, coverage stores sets of line numbers in SQLite using a packed binary representation called a numbits. A numbits is a set of positive integers.

A numbits is stored as a blob in the database. The exact meaning of the bytes in the blobs should be considered an implementation detail that might change in the future. Use these functions to work with those binary blobs of data.

`coverage.numbits.num_in_numbits` (*num*, *numbits*)

Does the integer *num* appear in *numbits*?

Returns A bool, True if *num* is a member of *numbits*.

`coverage.numbits.numbits_any_intersection` (*numbits1*, *numbits2*)

Is there any number that appears in both numbits?

Determine whether two number sets have a non-empty intersection. This is faster than computing the intersection.

Returns A bool, True if there is any number in both *numbits1* and *numbits2*.

`coverage.numbits.numbits_intersection` (*numbits1*, *numbits2*)

Compute the intersection of two numbits.

Returns A new numbits, the intersection *numbits1* and *numbits2*.

`coverage.numbits.numbits_to_nums` (*numbits*)

Convert a numbits into a list of numbers.

Parameters *numbits* – a binary blob, the packed number set.

Returns A list of ints.

When registered as a SQLite function by `register_sqlite_functions()`, this returns a string, a JSON-encoded list of ints.

`coverage.numbits.numbits_union(numbits1, numbits2)`

Compute the union of two numbits.

Returns A new numbits, the union of *numbits1* and *numbits2*.

`coverage.numbits.nums_to_numbits(nums)`

Convert *nums* into a numbits.

Parameters *nums* – a reusable iterable of integers, the line numbers to store.

Returns A binary blob.

`coverage.numbits.register_sqlite_functions(connection)`

Define numbits functions in a SQLite connection.

This defines these functions for use in SQLite statements:

- `numbits_union()`
- `numbits_intersection()`
- `numbits_any_intersection()`
- `num_in_numbits()`
- `numbits_to_nums()`

connection is a `sqlite3.Connection` object. After creating the connection, pass it to this function to register the numbits functions. Then you can use numbits functions in your queries:

```
import sqlite3
from coverage.numbits import register_sqlite_functions

conn = sqlite3.connect('example.db')
register_sqlite_functions(conn)
c = conn.cursor()
# Kind of a nonsense query: find all the files and contexts that
# executed line 47 in any file:
c.execute(
    "select file_id, context_id from line_bits where num_in_numbits(?, numbits)",
    (47,)
)
```

5.10 How coverage.py works

For advanced use of coverage.py, or just because you are curious, it helps to understand what's happening behind the scenes.

Coverage.py works in three phases:

- **Execution:** Coverage.py runs your code, and monitors it to see what lines were executed.
- **Analysis:** Coverage.py examines your code to determine what lines could have run.
- **Reporting:** Coverage.py combines the results of execution and analysis to produce a coverage number and an indication of missing execution.

The execution phase is handled by the `coverage run` command. The analysis and reporting phases are handled by the reporting commands like `coverage report` or `coverage html`.

As a short-hand, I say that `coverage.py` measures what lines were executed. But it collects more information than that. It can measure what branches were taken, and if you have contexts enabled, for each line or branch, it will also measure what contexts they were executed in.

Let's look at each phase in more detail.

5.10.1 Execution

At the heart of the execution phase is a trace function. This is a function that the Python interpreter invokes for each line executed in a program. Coverage.py implements a trace function that records each file and line number as it is executed.

For more details of trace functions, see the Python docs for `sys.settrace`, or if you are really brave, [How C trace functions really work](#).

Executing a function for every line in your program can make execution very slow. Coverage.py's trace function is implemented in C to reduce that overhead. It also takes care to not trace code that you aren't interested in.

When measuring branch coverage, the same trace function is used, but instead of recording line numbers, coverage.py records pairs of line numbers. Each invocation of the trace function remembers the line number, then the next invocation records the pair (*prev*, *this*) to indicate that execution transitioned from the previous line to this line. Internally, these are called arcs.

As the data is being collected, coverage.py writes the data to a file, usually named `.coverage`. This is a *SQLite database* containing all of the measured data.

Plugins

Of course coverage.py mostly measures execution of Python files. But it can also be used to analyze other kinds of execution. *File tracer plugins* provide support for non-Python files. For example, Django HTML templates result in Python code being executed somewhere, but as a developer, you want that execution mapped back to your `.html` template file.

During execution, each new Python file encountered is provided to the plugins to consider. A plugin can claim the file and then convert the runtime Python execution into source-level data to be recorded.

Dynamic contexts

When using *dynamic contexts*, there is a current dynamic context that changes over the course of execution. It starts as empty. While it is empty, every time a new function is entered, a check is made to see if the dynamic context should change. While a non-empty dynamic context is current, the check is skipped until the function that started the context returns.

5.10.2 Analysis

After your program has been executed and the line numbers recorded, coverage.py needs to determine what lines could have been executed. Luckily, compiled Python files (.pyc files) have a table of line numbers in them. Coverage.py reads this table to get the set of executable lines, with a little more source analysis to leave out things like docstrings.

The data file is read to get the set of lines that were executed. The difference between the executable lines and the executed lines are the lines that were not executed.

The same principle applies for branch measurement, though the process for determining possible branches is more involved. Coverage.py uses the abstract syntax tree of the Python source file to determine the set of possible branches.

5.10.3 Reporting

Once we have the set of executed lines and missing lines, reporting is just a matter of formatting that information in a useful way. Each reporting method (text, HTML, JSON, annotated source, XML) has a different output format, but the process is the same: write out the information in the particular format, possibly including the source code itself.

5.11 Plug-ins

Coverage.py's behavior can be extended with third-party plug-ins. A plug-in is a separately installed Python class that you register in your .coveragerc. Plugins can alter a number of aspects of coverage.py's behavior, including implementing coverage measurement for non-Python files.

Information about using plug-ins is on this page. To write a plug-in, see [Plug-in classes](#).

New in version 4.0.

5.11.1 Using plug-ins

To use a coverage.py plug-in, you install it and configure it. For this example, let's say there's a Python package called something that provides a coverage.py plug-in called something.plugin.

1. Install the plug-in's package as you would any other Python package:

```
pip install something
```

2. Configure coverage.py to use the plug-in. You do this by editing (or creating) your .coveragerc file, as described in [Configuration reference](#). The plugins setting indicates your plug-in. It's a list of importable module names of plug-ins:

```
[run]
plugins =
    something.plugin
```

3. If the plug-in needs its own configuration, you can add those settings in the .coveragerc file in a section named for the plug-in:

```
[something.plugin]
option1 = True
option2 = abc.foo
```

Check the documentation for the plug-in for details on the options it takes.

4. Run your tests with coverage.py as you usually would. If you get a message like “Plugin file tracers (something.plugin) aren’t supported with PyTracer,” then you don’t have the *C extension* installed. The C extension is needed for certain plug-ins.

5.11.2 Available plug-ins

Some coverage.py plug-ins you might find useful:

- [Django template coverage.py plug-in](#): for measuring coverage in Django templates.
- [Conditional coverage plug-in](#): for measuring coverage based on any rules you define! Can exclude different lines of code that are only executed on different platforms, python versions, and with different dependencies installed.
- [Mako template coverage plug-in](#): for measuring coverage in Mako templates. Doesn’t work yet, probably needs some changes in Mako itself.

5.12 Contributing to coverage.py

I welcome contributions to coverage.py. Over the years, dozens of people have provided patches of various sizes to add features or fix bugs. This page should have all the information you need to make a contribution.

One source of history or ideas are the [bug reports](#) against coverage.py. There you can find ideas for requested features, or the remains of rejected ideas.

5.12.1 Before you begin

If you have an idea for coverage.py, run it by me before you begin writing code. This way, I can get you going in the right direction, or point you to previous work in the area. Things are not always as straightforward as they seem, and having the benefit of lessons learned by those before you can save you frustration.

5.12.2 Getting the code

The coverage.py code is hosted on a GitHub repository at <https://github.com/nedbat/coveragepy>. To get a working environment, follow these steps:

1. (Optional, but recommended) Create a Python 3.6 virtualenv to work in, and activate it.

1. Clone the repository:

```
$ git clone https://github.com/nedbat/coveragepy
$ cd coveragepy
```

2. Install the requirements:

```
$ pip install -r requirements/dev.pip
```

3. Install a number of versions of Python. Coverage.py supports a wide range of Python versions. The more you can test with, the more easily your code can be used as-is. If you only have one version, that’s OK too, but may mean more work integrating your contribution.

5.12.3 Running the tests

The tests are written mostly as standard unittest-style tests, and are run with pytest running under tox:

```
$ tox
py27 develop-inst-noop: /Users/ned/coverage/trunk
py27 installed: DEPRECATION: Python 2.7 will reach the end of its life on January 1st,

----- summary -----
py27: commands succeeded

```

(continues on next page)

(continued from previous page)

```
py36: commands succeeded
congratulations :)
```

Tox runs the complete test suite twice for each version of Python you have installed. The first run uses the Python implementation of the trace function, the second uses the C implementation.

To limit tox to just a few versions of Python, use the `-e` switch:

```
$ tox -e py27,py37
```

To run just a few tests, you can use [pytest test selectors](#):

```
$ tox tests/test_misc.py
$ tox tests/test_misc.py::HasherTest
$ tox tests/test_misc.py::HasherTest::test_string_hashing
```

These command run the tests in one file, one class, and just one test, respectively.

You can also affect the test runs with environment variables. Define any of these as 1 to use them:

- `COVERAGE_NO_PYTRACER`: disables the Python tracer if you only want to run the CTracer tests.
- `COVERAGE_NO_CTRACER`: disables the C tracer if you only want to run the PyTracer tests.
- `COVERAGE_AST_DUMP`: will dump the AST tree as it is being used during code parsing.
- `COVERAGE_KEEP_TMP`: keeps the temporary directories in which tests are run. This makes debugging tests easier. The temporary directories are at `$TMPDIR/coverage_test/*`, and are named for the test that made them.

Of course, run all the tests on every version of Python you have, before submitting a change.

5.12.4 Lint, etc

I try to keep the coverage.py as clean as possible. I use pylint to alert me to possible problems:

```
$ make lint
pylint coverage setup.py tests
python -m tabnanny coverage setup.py tests
python igor.py check_eol
```

The source is pylint-clean, even if it's because there are pragmas quieting some warnings. Please try to keep it that way, but don't let pylint warnings keep you from sending patches. I can clean them up.

Lines should be kept to a 100-character maximum length. I recommend an editorconfig.org plugin for your editor of choice.

Other style questions are best answered by looking at the existing code. Formatting of docstrings, comments, long lines, and so on, should match the code that already exists.

5.12.5 Coverage testing coverage.py

Coverage.py can measure itself, but it's complicated. The process has been packaged up to make it easier:

```
$ make metacov metahtml
```

Then look at `htmlcov/index.html`. Note that due to the recursive nature of coverage.py measuring itself, there are some parts of the code that will never appear as covered, even though they are executed.

5.12.6 Contributing

When you are ready to contribute a change, any way you can get it to me is probably fine. A pull request on GitHub is great, but a simple diff or patch works too.

5.13 Things that cause trouble

Coverage.py works well, and I want it to properly measure any Python program, but there are some situations it can't cope with. This page details some known problems, with possible courses of action, and links to coverage.py bug reports with more information.

I would love to *hear from you* if you have information about any of these problems, even just to explain to me why you want them to start working properly.

If your problem isn't discussed here, you can of course search the [coverage.py bug tracker](#) directly to see if there is some mention of it.

5.13.1 Things that don't work

There are a number of popular modules, packages, and libraries that prevent coverage.py from working properly:

- `execv`, or one of its variants. These end the current program and replace it with a new one. This doesn't save the collected coverage data, so your program that calls `execv` will not be fully measured. A patch for coverage.py is in [issue 43](#).
- `thread`, in the Python standard library, is the low-level threading interface. Threads created with this module will not be traced. Use the higher-level `threading` module instead.
- `sys.settrace` is the Python feature that coverage.py uses to see what's happening in your program. If another part of your program is using `sys.settrace`, then it will conflict with coverage.py, and it won't be measured properly.

5.13.2 Still having trouble?

If your problem isn't mentioned here, and isn't already reported in the [coverage.py bug tracker](#), please *get in touch with me*, we'll figure out a solution.

5.14 FAQ and other help

5.14.1 Frequently asked questions

Q: Why do unexecutable lines show up as executed?

Usually this is because you've updated your code and run coverage.py on it again without erasing the old data. Coverage.py records line numbers executed, so the old data may have recorded a line number which has since moved, causing coverage.py to claim a line has been executed which cannot be.

If old data is persisting, you can use an explicit `coverage erase` command to clean out the old data.

Q: Why do the bodies of functions show as executed, but the def lines do not?

This happens because coverage.py is started after the functions are defined. The definition lines are executed without coverage measurement, then coverage.py is started, then the function is called. This means the body is measured, but the definition of the function itself is not.

The same thing can happen with the bodies of classes.

To fix this, start coverage.py earlier. If you use the *command line* to run your program with coverage.py, then your entire program will be monitored. If you are using the *API*, you need to call `coverage.start()` before importing the modules that define your functions.

Q: My decorator lines are marked as covered, but the “def” line is not. Why?

Different versions of Python report execution on different lines. Coverage.py adapts its behavior to the version of Python being used. In Python 3.7 and earlier, a decorated function definition only reported the decorator as executed. In Python 3.8 and later, both the decorator and the “def” are reported. If you collect execution data on Python 3.7, and then run coverage reports on Python 3.8, there will be a discrepancy.

Q: How is the total percentage calculated?

Coverage.py counts the total number of possible executions. This is the number of executable statements minus the number of excluded statements. It then counts the number of those possibilities that were actually executed. The total percentage is the actual executions divided by the possible executions.

As an example, a coverage report with 1514 statements and 901 missed statements would calculate a total percentage of $(1514-901)/1514$, or 40.49%.

Branch coverage extends the calculation to include the total number of possible branch exits, and the number of those taken. In this case the specific numbers shown in coverage reports don't calculate out to the percentage shown, because the number of missing branch exits isn't reported explicitly. A branch line that wasn't executed at all is counted once as a missing statement in the report, instead of as two missing branches. Reports show the number of partial branches, which is the lines that were executed but did not execute all of their exits.

Q: Coverage.py is much slower than I remember, what's going on?

Make sure you are using the C trace function. Coverage.py provides two implementations of the trace function. The C implementation runs much faster. To see what you are running, use `coverage debug sys`. The output contains details of the environment, including a line that says either `tracer: CTracer` or `tracer: PyTracer`. If it says `PyTracer` then you are using the slow Python implementation.

Try re-installing coverage.py to see what happened and if you get the CTracer as you should.

Q: Isn't coverage testing the best thing ever?

It's good, but it isn't perfect.

Q: Where can I get more help with coverage.py?

You can discuss coverage.py or get help using it on the [Testing In Python](#) mailing list.

Bug reports are gladly accepted at the [GitHub issue tracker](#).

I can be reached in a number of ways, I'm happy to answer questions about using coverage.py.

5.14.2 History

Coverage.py was originally written by [Gareth Rees](#). Since 2004, [Ned Batchelder](#) has extended and maintained it with the help of many others. The [change history](#) has all the details.

5.15 Major changes in 5.0

This is an overview of the changes in 5.0 since the last version of 4.5.x. This is not a complete list of all changes. See the [complete change history](#) for all the details.

5.15.1 Open Questions

- How to support SQL access to data? The database schema has to be convenient and efficient for coverage.py's execution, which would naturally make it an internal implementation detail. But the coverage data is now more complex, and SQL access could be a powerful way to access it, pointing toward a public guaranteed schema. What's the right balance?

5.15.2 Backward Incompatibilities

- Python 2.6, 3.3 and 3.4 are no longer supported.
- The `CoverageData` interface is still public, but has changed.
- The data file is now created earlier than it used to be. In some circumstances, you may need to use `parallel=true` to avoid multiple processes overwriting each others' data.
- When constructing a `coverage.Coverage` object, `data_file` can be specified as `None` to prevent writing any data file at all. In previous versions, an explicit `data_file=None` argument would use the default of `".coverage"`. Fixes [issue 871](#).

- The `[run] note` setting has been deprecated. Using it will result in a warning, and the note will not be written to the data file. The corresponding `CoverageData` methods have been removed.
- The deprecated `Reporter.file_reporters` property has been removed.
- The reporting methods used to permanently apply their arguments to the configuration of the Coverage object. Now they no longer do. The arguments affect the operation of the method, but do not persist.
- Many internal attributes and functions were changed. These were not part of the public supported API. If your code used them, it might now stop working.

5.15.3 New Features

- Coverage.py can now record the context in which each line was executed. The contexts are stored in the data file and can be used to drill down into why a particular line was run. Static contexts let you specify a label for an entire coverage run, for example to separate coverage for different operating systems or versions of Python. Dynamic contexts can change during a single measurement run. This can be used to record the names of the tests that executed each line. See *Measurement contexts* for full information.
- Coverage’s data storage has changed. In version 4.x, `.coverage` files were basically JSON. Now, they are SQLite databases. The database schema is documented (*Coverage.py database schema*), but might still be in flux.
- Data can now be “reported” in JSON format, for programmatic use, as requested in [issue 720](#). The new `coverage json` command writes raw and summarized data to a JSON file. Thanks, Matt Bachmann.
- Configuration can now be read from TOML files. This requires installing coverage.py with the `[toml]` extra. The standard “`pyproject.toml`” file will be read automatically if no other configuration file is found, with settings in the `[tool.coverage.]` namespace. Thanks to Frazer McLean for implementation and persistence. Finishes [issue 664](#).
- The HTML and textual reports now have a `--skip-empty` option that skips files with no statements, notably `__init__.py` files. Thanks, Reya B.
- You can specify the command line to run your program with the `[run] command_line` configuration setting, as requested in [issue 695](#).
- An experimental `[run] relative_files` setting tells coverage to store relative file names in the data file. This makes it easier to run tests in one (or many) environments, and then report in another. It has not had much real-world testing, so it may change in incompatible ways in the future.
- Environment variable substitution in configuration files now supports two syntaxes for controlling the behavior of undefined variables: if `VARNAME` is not defined, `${VARNAME?}` will raise an error, and `${VARNAME-default value}` will use “default value”.
- The location of the configuration file can now be specified with a `COVERAGE_RCFILE` environment variable, as requested in [issue 650](#).
- A new warning (`already-imported`) is issued if measurable files have already been imported before coverage.py started measurement. See *Warnings* for more information.
- Error handling during reporting has changed slightly. All reporting methods now behave the same. The `--ignore-errors` option keeps errors from stopping the reporting, but files that couldn’t parse as Python will always be reported as warnings. As with other warnings, you can suppress them with the `[run] disable_warnings` configuration setting.
- Added the classmethod `Coverage.current()` to get the latest started Coverage instance.

5.15.4 Bugs Fixed

- The `coverage run` command has always adjusted the first entry in `sys.path`, to properly emulate how Python runs your program. Now this adjustment is skipped if `sys.path[0]` is already different than Python's default. This fixes [issue 715](#).
- Python files run with `-m` now have `__spec__` defined properly. This fixes [issue 745](#) (about not being able to run unittest tests that spawn subprocesses), and [issue 838](#), which described the problem directly.
- Coverage will create directories as needed for the data file if they don't exist, closing [issue 721](#).
- `fail_under` values more than 100 are reported as errors. Thanks to Mike Fiedler for closing [issue 746](#).
- The “missing” values in the text output are now sorted by line number, so that missing branches are reported near the other lines they affect. The values used to show all missing lines, and then all missing branches.
- Coverage.py no longer fails if the user program deletes its current directory. Fixes [issue 806](#). Thanks, Dan Hemberger.

5.16 Change history for coverage.py

These changes are listed in decreasing version number order. Note this can be different from a strict chronological order when there are two branches in development at the same time, such as 4.5.x and 5.0.

This list is detailed and covers changes in each pre-release version. If you want to know what's different in 5.0 since 4.5.x, see [Major changes in 5.0](#).

5.16.1 Unreleased

- The text report produced by `coverage report` now always outputs a TOTAL line, even if only one Python file is reported. This makes regex parsing of the output easier. Thanks, Judson Neer. This had been requested a number of times ([issue 1086](#), [issue 922](#), [issue 732](#)).
- The `skip_covered` and `skip_empty` settings in the configuration file can now be specified in the `[html]` section, so that text reports and HTML reports can use separate settings. The HTML report will still use the `[report]` settings if there isn't a value in the `[html]` section. Closes [issue 1090](#).
- Combining files on Windows across drives now works properly, fixing [issue 577](#). Thanks, [Valentine Lab](#).
- Fix an obscure warning from deep in the `_decimal` module, as reported in [issue 1084](#).
- Update to support Python 3.10 alphas in progress, including [PEP 626: Precise line numbers for debugging and other tools](#).

5.16.2 Version 5.3.1 — 2020-12-19

- When using `--source` on a large source tree, v5.x was slower than previous versions. This performance regression is now fixed, closing [issue 1037](#).
- Mysterious SQLite errors can happen on PyPy, as reported in [issue 1010](#). An immediate retry seems to fix the problem, although it is an unsatisfying solution.
- The HTML report now saves the sort order in a more widely supported way, fixing [issue 986](#). Thanks, Sebastián Ramírez ([pull request 1066](#)).

- The HTML report pages now have a *Sleepy Snake* favicon.
- Wheels are now provided for manylinux2010, and for PyPy3 (pp36 and pp37).
- Continuous integration has moved from Travis and AppVeyor to GitHub Actions.

5.16.3 Version 5.3 — 2020-09-13

- The `source` setting has always been interpreted as either a file path or a module, depending on which existed. If both interpretations were valid, it was assumed to be a file path. The new `source_pkgs` setting can be used to name a package to disambiguate this case. Thanks, Thomas Grainger. Fixes [issue 268](#).
- If a plugin was disabled due to an exception, we used to still try to record its information, causing an exception, as reported in [issue 1011](#). This is now fixed.

5.16.4 Version 5.2.1 — 2020-07-23

- The dark mode HTML report still used light colors for the context listing, making them unreadable ([issue 1009](#)). This is now fixed.
- The time stamp on the HTML report now includes the time zone. Thanks, Xie Yanbo ([pull request 960](#)).

5.16.5 Version 5.2 — 2020-07-05

- The HTML report has been redesigned by Vince Salvino. There is now a dark mode, the code text is larger, and system sans serif fonts are used, in addition to other small changes ([issue 858](#) and [pull request 931](#)).
- The `coverage report` and `coverage html` commands now accept a `--precision` option to control the number of decimal points displayed. Thanks, Teake Nutma ([pull request 982](#)).
- The `coverage report` and `coverage html` commands now accept a `--no-skip-covered` option to negate `--skip-covered`. Thanks, Anthony Sottile ([issue 779](#) and [pull request 932](#)).
- The `--skip-empty` option is now available for the XML report, closing [issue 976](#).
- The `coverage report` command now accepts a `--sort` option to specify how to sort the results. Thanks, Jerin Peter George ([pull request 1005](#)).
- If coverage fails due to the coverage total not reaching the `--fail-under` value, it will now print a message making the condition clear. Thanks, Naveen Yadav ([pull request 977](#)).
- TOML configuration files with non-ASCII characters would cause errors on Windows ([issue 990](#)). This is now fixed.
- The output of `--debug=trace` now includes information about how the `--source` option is being interpreted, and the module names being considered.

5.16.6 Version 5.1 — 2020-04-12

- The JSON report now includes counts of covered and missing branches. Thanks, Salvatore Zagaria.
- On Python 3.8, `try-finally-return` reported wrong branch coverage with decorated async functions ([issue 964](#)). This is now fixed. Thanks, Kjell Braden.
- The `get_option()` and `set_option()` methods can now manipulate the `[paths]` configuration setting. Thanks to Bernát Gábor for the fix for [issue 967](#).

5.16.7 Version 5.0.4 — 2020-03-16

- If using the `[run] relative_files` setting, the XML report will use relative files in the `<source>` elements indicating the location of source code. Closes [issue 948](#).
- The textual summary report could report missing lines with negative line numbers on PyPy3 7.1 ([issue 943](#)). This is now fixed.
- Windows wheels for Python 3.8 were incorrectly built, but are now fixed. ([issue 949](#))
- Updated Python 3.9 support to 3.9a4.
- HTML reports couldn't be sorted if `localStorage` wasn't available. This is now fixed: sorting works even though the sorting setting isn't retained. ([issue 944](#) and [pull request 945](#)). Thanks, Abdeali Kothari.

5.16.8 Version 5.0.3 — 2020-01-12

- A performance improvement in 5.0.2 didn't work for test suites that changed directory before combining data, causing "Couldn't use data file: no such table: meta" errors ([issue 916](#)). This is now fixed.
- Coverage could fail to run your program with some form of "ModuleNotFound" or "ImportError" trying to import from the current directory. This would happen if coverage had been packaged into a zip file (for example, on Windows), or was found indirectly (for example, by `pyenv-virtualenv`). A number of different scenarios were described in [issue 862](#) which is now fixed. Huge thanks to Agbonze O. Jeremiah for reporting it, and Alexander Waters and George-Cristian Bîrzan for protracted debugging sessions.
- Added the "premain" debug option.
- Added SQLite compile-time options to the "debug sys" output.

5.16.9 Version 5.0.2 — 2020-01-05

- Programs that used multiprocessing and changed directories would fail under coverage. This is now fixed ([issue 890](#)). A side effect is that debug information about the config files read now shows absolute paths to the files.
- When running programs as modules (`coverage run -m`) with `--source`, some measured modules were imported before coverage starts. This resulted in unwanted warnings ("Already imported a file that will be measured") and a reduction in coverage totals ([issue 909](#)). This is now fixed.
- If no data was collected, an exception about "No data to report" could happen instead of a 0% report being created ([issue 884](#)). This is now fixed.
- The handling of source files with non-encodable file names has changed. Previously, if a file name could not be encoded as UTF-8, an error occurred, as described in [issue 891](#). Now, those files will not be measured, since their data would not be recordable.
- A new warning ("dynamic-conflict") is issued if two mechanisms are trying to change the dynamic context. Closes [issue 901](#).

- `coverage run --debug=sys` would fail with an `AttributeError`. This is now fixed ([issue 907](#)).

5.16.10 Version 5.0.1 — 2019-12-22

- If a 4.x data file is the cause of a “file is not a database” error, then use a more specific error message, “Looks like a coverage 4.x data file, are you mixing versions of coverage?” Helps diagnose the problems described in [issue 886](#).
- Measurement contexts and relative file names didn’t work together, as reported in [issue 899](#) and [issue 900](#). This is now fixed, thanks to David Szotten.
- When using `coverage run --concurrency=multiprocessing`, all data files should be named with parallel-ready suffixes. 5.0 mistakenly named the main process’ file with no suffix when using `--append`. This is now fixed, closing [issue 880](#).
- Fixed a problem on Windows when the current directory is changed to a different drive ([issue 895](#)). Thanks, Olivier Grisel.
- Updated Python 3.9 support to 3.9a2.

5.16.11 Version 5.0 — 2019-12-14

Nothing new beyond 5.0b2.

5.16.12 Version 5.0b2 — 2019-12-08

- An experimental `[run] relative_files` setting tells coverage to store relative file names in the data file. This makes it easier to run tests in one (or many) environments, and then report in another. It has not had much real-world testing, so it may change in incompatible ways in the future.
- When constructing a `coverage.Coverage` object, `data_file` can be specified as `None` to prevent writing any data file at all. In previous versions, an explicit `data_file=None` argument would use the default of “coverage”. Fixes [issue 871](#).
- Python files run with `-m` now have `__spec__` defined properly. This fixes [issue 745](#) (about not being able to run unittest tests that spawn subprocesses), and [issue 838](#), which described the problem directly.
- The `[paths]` configuration section is now ordered. If you specify more than one list of patterns, the first one that matches will be used. Fixes [issue 649](#).
- The `coverage.numbits.register_sqlite_functions()` function now also registers `numbits_to_nums` for use in SQLite queries. Thanks, Simon Willison.
- Python 3.9a1 is supported.
- Coverage.py has a mascot: *Sleepy Snake*.

5.16.13 Version 5.0b1 — 2019-11-11

- The HTML and textual reports now have a `--skip-empty` option that skips files with no statements, notably `__init__.py` files. Thanks, Reya B.
- Configuration can now be read from TOML files. This requires installing coverage.py with the `[toml]` extra. The standard “pyproject.toml” file will be read automatically if no other configuration file is found, with settings in the `[tool.coverage.]` namespace. Thanks to Frazer McLean for implementation and persistence. Finishes [issue 664](#).
- The `[run] note` setting has been deprecated. Using it will result in a warning, and the note will not be written to the data file. The corresponding `CoverageData` methods have been removed.
- The HTML report has been reimplemented (no more table around the source code). This allowed for a better presentation of the context information, hopefully resolving [issue 855](#).
- Added sqlite3 module version information to `coverage debug sys` output.
- Asking the HTML report to show contexts (`[html] show_contexts=True` or `coverage html --show-contexts`) will issue a warning if there were no contexts measured ([issue 851](#)).

5.16.14 Version 5.0a8 — 2019-10-02

- The `CoverageData` API has changed how queries are limited to specific contexts. Now you use `CoverageData.set_query_context()` to set a single exact-match string, or `CoverageData.set_query_contexts()` to set a list of regular expressions to match contexts. This changes the command-line `--contexts` option to use regular expressions instead of filename-style wildcards.

5.16.15 Version 5.0a7 — 2019-09-21

- Data can now be “reported” in JSON format, for programmatic use, as requested in [issue 720](#). The new `coverage json` command writes raw and summarized data to a JSON file. Thanks, Matt Bachmann.
- Dynamic contexts are now supported in the Python tracer, which is important for PyPy users. Closes [issue 846](#).
- The compact line number representation introduced in 5.0a6 is called a “numbits.” The `coverage.numbits` module provides functions for working with them.
- The reporting methods used to permanently apply their arguments to the configuration of the Coverage object. Now they no longer do. The arguments affect the operation of the method, but do not persist.
- A class named “test_something” no longer confuses the `test_function` dynamic context setting. Fixes [issue 829](#).
- Fixed an unusual tokenizing issue with backslashes in comments. Fixes [issue 822](#).
- `debug=plugin` didn’t properly support configuration or dynamic context plugins, but now it does, closing [issue 834](#).

5.16.16 Version 5.0a6 — 2019-07-16

- Reporting on contexts. Big thanks to Stephan Richter and Albertas Agejevas for the contribution.
 - The `--contexts` option is available on the `report` and `html` commands. It’s a comma-separated list of shell-style wildcards, selecting the contexts to report on. Only contexts matching one of the wildcards will be included in the report.
 - The `--show-contexts` option for the `html` command adds context information to each covered line. Hovering over the “ctx” marker at the end of the line reveals a list of the contexts that covered the line.
- Database changes:
 - Line numbers are now stored in a much more compact way. For each file and context, a single binary string is stored with a bit per line number. This greatly improves memory use, but makes ad-hoc use difficult.
 - Dynamic contexts with no data are no longer written to the database.
 - SQLite data storage is now faster. There’s no longer a reason to keep the JSON data file code, so it has been removed.
- Changes to the `CoverageData` interface:
 - The new `CoverageData.dumps()` method serializes the data to a string, and a corresponding `CoverageData.loads()` method reconstitutes this data. The format of the data string is subject to change at any time, and so should only be used between two installations of the same version of coverage.py.
 - The `CoverageData` constructor has a new argument, `no_disk` (default: False). Setting it to True prevents writing any data to the disk. This is useful for transient data objects.
- Added the classmethod `Coverage.current()` to get the latest started Coverage instance.
- Multiprocessing support in Python 3.8 was broken, but is now fixed. Closes [issue 828](#).
- Error handling during reporting has changed slightly. All reporting methods now behave the same. The `--ignore-errors` option keeps errors from stopping the reporting, but files that couldn’t parse as Python will always be reported as warnings. As with other warnings, you can suppress them with the `[run] disable_warnings` configuration setting.
- Coverage.py no longer fails if the user program deletes its current directory. Fixes [issue 806](#). Thanks, Dan Hemberger.
- The scrollbar markers in the HTML report now accurately show the highlighted lines, regardless of what categories of line are highlighted.
- The hack to accommodate [ShiningPanda](#) looking for an obsolete internal data file has been removed, since [ShiningPanda 0.22](#) fixed it four years ago.
- The deprecated `Reporter.file_reporters` property has been removed.

5.16.17 Version 5.0a5 — 2019-05-07

- Drop support for Python 3.4
- Dynamic contexts can now be set two new ways, both thanks to Justas Sadzevičius.
 - A plugin can implement a `dynamic_context` method to check frames for whether a new context should be started. See [Dynamic Context Switchers](#) for more details.
 - Another tool (such as a test runner) can use the new `Coverage.switch_context()` method to explicitly change the context.

- The `dynamic_context = test_function` setting now works with Python 2 old-style classes, though it only reports the method name, not the class it was defined on. Closes [issue 797](#).
- `fail_under` values more than 100 are reported as errors. Thanks to Mike Fiedler for closing [issue 746](#).
- The “missing” values in the text output are now sorted by line number, so that missing branches are reported near the other lines they affect. The values used to show all missing lines, and then all missing branches.
- Access to the SQLite database used for data storage is now thread-safe. Thanks, Stephan Richter. This closes [issue 702](#).
- Combining data stored in SQLite is now about twice as fast, fixing [issue 761](#). Thanks, Stephan Richter.
- The `filename` attribute on `CoverageData` objects has been made private. You can use the `data_filename` method to get the actual file name being used to store data, and the `base_filename` method to get the original filename before parallelizing suffixes were added. This is part of fixing [issue 708](#).
- Line numbers in the HTML report now align properly with source lines, even when Chrome’s minimum font size is set, fixing [issue 748](#). Thanks Wen Ye.

5.16.18 Version 5.0a4 — 2018-11-25

- You can specify the command line to run your program with the `[run] command_line` configuration setting, as requested in [issue 695](#).
- Coverage will create directories as needed for the data file if they don’t exist, closing [issue 721](#).
- The `coverage run` command has always adjusted the first entry in `sys.path`, to properly emulate how Python runs your program. Now this adjustment is skipped if `sys.path[0]` is already different than Python’s default. This fixes [issue 715](#).
- Improvements to context support:
 - The “no such table: meta” error is fixed.: [issue 716](#).
 - Combining data files is now much faster.
- Python 3.8 (as of today!) passes all tests.

5.16.19 Version 5.0a3 — 2018-10-06

- Context support: static contexts let you specify a label for a coverage run, which is recorded in the data, and retained when you combine files. See [Measurement contexts](#) for more information.
- Dynamic contexts: specifying `[run] dynamic_context = test_function` in the config file will record the test function name as a dynamic context during execution. This is the core of “Who Tests What” ([issue 170](#)). Things to note:
 - There is no reporting support yet. Use SQLite to query the `.coverage` file for information. Ideas are welcome about how reporting could be extended to use this data.
 - There’s a noticeable slow-down before any test is run.
 - Data files will now be roughly N times larger, where N is the number of tests you have. Combining data files is therefore also N times slower.
 - No other values for `dynamic_context` are recognized yet. Let me know what else would be useful. I’d like to use a pytest plugin to get better information directly from pytest, for example.

- Environment variable substitution in configuration files now supports two syntaxes for controlling the behavior of undefined variables: if `VARNAME` is not defined, `${VARNAME?}` will raise an error, and `${VARNAME-default value}` will use “default value”.
- Partial support for Python 3.8, which has not yet released an alpha. Fixes [issue 707](#) and [issue 714](#).

5.16.20 Version 5.0a2 — 2018-09-03

- Coverage’s data storage has changed. In version 4.x, `.coverage` files were basically JSON. Now, they are SQLite databases. This means the data file can be created earlier than it used to. A large amount of code was refactored to support this change.
 - Because the data file is created differently than previous releases, you may need `parallel=true` where you didn’t before.
 - The old data format is still available (for now) by setting the environment variable `COVERAGE_STORAGE=json`. Please tell me if you think you need to keep the JSON format.
 - The database schema is guaranteed to change in the future, to support new features. I’m looking for opinions about making the schema part of the public API to `coverage.py` or not.
- Development moved from [Bitbucket](#) to [GitHub](#).
- HTML files no longer have trailing and extra whitespace.
- The sort order in the HTML report is stored in local storage rather than cookies, closing [issue 611](#). Thanks, Federico Bond.
- `pickle2json`, for converting v3 data files to v4 data files, has been removed.

5.16.21 Version 5.0a1 — 2018-06-05

- Coverage.py no longer supports Python 2.6 or 3.3.
- The location of the configuration file can now be specified with a `COVERAGE_RCFILE` environment variable, as requested in [issue 650](#).
- Namespace packages are supported on Python 3.7, where they used to cause `TypeError`s about path being `None`. Fixes [issue 700](#).
- A new warning (`already-imported`) is issued if measurable files have already been imported before `coverage.py` started measurement. See [Warnings](#) for more information.
- Running coverage many times for small runs in a single process should be faster, closing [issue 625](#). Thanks, David MacIver.
- Large HTML report pages load faster. Thanks, Pankaj Pandey.

5.16.22 Version 4.5.4 — 2019-07-29

- Multiprocessing support in Python 3.8 was broken, but is now fixed. Closes [issue 828](#).

5.16.23 Version 4.5.3 — 2019-03-09

- Only packaging metadata changes.

5.16.24 Version 4.5.2 — 2018-11-12

- Namespace packages are supported on Python 3.7, where they used to cause `TypeError`s about path being `None`. Fixes [issue 700](#).
- Python 3.8 (as of today!) passes all tests. Fixes [issue 707](#) and [issue 714](#).
- Development moved from [Bitbucket](#) to [GitHub](#).

5.16.25 Version 4.5.1 — 2018-02-10

- Now that 4.5 properly separated the `[run] omit` and `[report] omit` settings, an old bug has become apparent. If you specified a package name for `[run] source`, then omit patterns weren't matched inside that package. This bug ([issue 638](#)) is now fixed.
- On Python 3.7, reporting about a decorated function with no body other than a docstring would crash `coverage.py` with an `IndexError` ([issue 640](#)). This is now fixed.
- Configurer plugins are now reported in the output of `--debug=sys`.

5.16.26 Version 4.5 — 2018-02-03

- A new kind of plugin is supported: configurers are invoked at start-up to allow more complex configuration than the `.coveragerc` file can easily do. See *Plug-in classes* for details. This solves the complex configuration problem described in [issue 563](#).
- The `fail_under` option can now be a float. Note that you must specify the `[report] precision` configuration option for the fractional part to be used. Thanks to Lars Hupfeldt Nielsen for help with the implementation. Fixes [issue 631](#).
- The `include` and `omit` options can be specified for both the `[run]` and `[report]` phases of execution. 4.4.2 introduced some incorrect interactions between those phases, where the options for one were confused for the other. This is now corrected, fixing [issue 621](#) and [issue 622](#). Thanks to Daniel Hahler for seeing more clearly than I could.
- The `coverage combine` command used to always overwrite the data file, even when no data had been read from apparently combinable files. Now, an error is raised if we thought there were files to combine, but in fact none of them could be used. Fixes [issue 629](#).
- The `coverage combine` command could get confused about path separators when combining data collected on Windows with data collected on Linux, as described in [issue 618](#). This is now fixed: the result path always uses the path separator specified in the `[paths]` result.
- On Windows, the HTML report could fail when source trees are deeply nested, due to attempting to create HTML filenames longer than the 250-character maximum. Now filenames will never get much larger than 200 characters, fixing [issue 627](#). Thanks to Alex Sandro for helping with the fix.

5.16.27 Version 4.4.2 — 2017-11-05

- Support for Python 3.7. In some cases, class and module docstrings are no longer counted in statement totals, which could slightly change your total results.
- Specifying both `--source` and `--include` no longer silently ignores the include setting, instead it displays a warning. Thanks, Loïc Dachary. Closes [issue 265](#) and [issue 101](#).
- Fixed a race condition when saving data and multiple threads are tracing ([issue 581](#)). It could produce a “dictionary changed size during iteration” `RuntimeError`. I believe this mostly but not entirely fixes the race condition. A true fix would likely be too expensive. Thanks, Peter Baughman for the debugging, and Olivier Grisel for the fix with tests.
- Configuration values which are file paths will now apply tilde-expansion, closing [issue 589](#).
- Now secondary config files like `tox.ini` and `setup.cfg` can be specified explicitly, and prefixed sections like `[coverage:run]` will be read. Fixes [issue 588](#).
- Be more flexible about the command name displayed by help, fixing [issue 600](#). Thanks, Ben Finney.

5.16.28 Version 4.4.1 — 2017-05-14

- No code changes: just corrected packaging for Python 2.7 Linux wheels.

5.16.29 Version 4.4 — 2017-05-07

- Reports could produce the wrong file names for packages, reporting `pkg.py` instead of the correct `pkg/__init__.py`. This is now fixed. Thanks, Dirk Thomas.
- XML reports could produce `<source>` and `<class>` lines that together didn’t specify a valid source file path. This is now fixed. ([issue 526](#))
- Namespace packages are no longer warned as having no code. ([issue 572](#))
- Code that uses `sys.settrace(sys.gettrace())` in a file that wasn’t being coverage-measured would prevent correct coverage measurement in following code. An example of this was running doctests programmatically. This is now fixed. ([issue 575](#))
- Errors printed by the `coverage` command now go to `stderr` instead of `stdout`.
- Running `coverage xml` in a directory named with non-ASCII characters would fail under Python 2. This is now fixed. ([issue 573](#))

5.16.30 Version 4.4b1 — 2017-04-04

- Some warnings can now be individually disabled. Warnings that can be disabled have a short name appended. The `[run] disable_warnings` setting takes a list of these warning names to disable. Closes both [issue 96](#) and [issue 355](#).
- The XML report now includes attributes from version 4 of the Cobertura XML format, fixing [issue 570](#).
- In previous versions, calling a method that used collected data would prevent further collection. For example, `save()`, `report()`, `html_report()`, and others would all stop collection. An explicit `start()` was needed to get it going again. This is no longer true. Now you can use the collected data and also continue measurement. Both [issue 79](#) and [issue 448](#) described this problem, and have been fixed.
- Plugins can now find unexecuted files if they choose, by implementing the `find_executable_files` method. Thanks, Emil Madsen.

- Minimal IronPython support. You should be able to run IronPython programs under `coverage run`, though you will still have to do the reporting phase with CPython.
- Coverage.py has long had a special hack to support CPython’s need to measure the coverage of the standard library tests. This code was not installed by kitted versions of coverage.py. Now it is.

5.16.31 Version 4.3.4 — 2017-01-17

- Fixing 2.6 in version 4.3.3 broke other things, because the too-tricky exception wasn’t properly derived from Exception, described in [issue 556](#). A newb mistake; it hasn’t been a good few days.

5.16.32 Version 4.3.3 — 2017-01-17

- Python 2.6 support was broken due to a testing exception imported for the benefit of the coverage.py test suite. Properly conditionalizing it fixed [issue 554](#) so that Python 2.6 works again.

5.16.33 Version 4.3.2 — 2017-01-16

- Using the `--skip-covered` option on an HTML report with 100% coverage would cause a “No data to report” error, as reported in [issue 549](#). This is now fixed; thanks, Loïc Dachary.
- If-statements can be optimized away during compilation, for example, `if 0:` or `if __debug__:`. Coverage.py had problems properly understanding these statements which existed in the source, but not in the compiled bytecode. This problem, reported in [issue 522](#), is now fixed.
- If you specified `--source` as a directory, then coverage.py would look for importable Python files in that directory, and could identify ones that had never been executed at all. But if you specified it as a package name, that detection wasn’t performed. Now it is, closing [issue 426](#). Thanks to Loïc Dachary for the fix.
- If you started and stopped coverage measurement thousands of times in your process, you could crash Python with a “Fatal Python error: deallocating None” error. This is now fixed. Thanks to Alex Groce for the bug report.
- On PyPy, measuring coverage in subprocesses could produce a warning: “Trace function changed, measurement is likely wrong: None”. This was spurious, and has been suppressed.
- Previously, coverage.py couldn’t start on Jython, due to that implementation missing the multiprocessing module ([issue 551](#)). This problem has now been fixed. Also, [issue 322](#) about not being able to invoke coverage conveniently, seems much better: `jython -m coverage run myprog.py` works properly.
- Let’s say you ran the HTML report over and over again in the same output directory, with `--skip-covered`. And imagine due to your heroic test-writing efforts, a file just achieved the goal of 100% coverage. With coverage.py 4.3, the old HTML file with the less-than-100% coverage would be left behind. This file is now properly deleted.

5.16.34 Version 4.3.1 — 2016-12-28

- Some environments couldn't install 4.3, as described in [issue 540](#). This is now fixed.
- The check for conflicting `--source` and `--include` was too simple in a few different ways, breaking a few perfectly reasonable use cases, described in [issue 541](#). The check has been reverted while we re-think the fix for [issue 265](#).

5.16.35 Version 4.3 — 2016-12-27

Special thanks to **Loïc Dachary**, who took an extraordinary interest in coverage.py and contributed a number of improvements in this release.

- Subprocesses that are measured with `automatic subprocess measurement` used to read in any pre-existing data file. This meant data would be incorrectly carried forward from run to run. Now those files are not read, so each subprocess only writes its own data. Fixes [issue 510](#).
- The `coverage combine` command will now fail if there are no data files to combine. The combine changes in 4.2 meant that multiple combines could lose data, leaving you with an empty .coverage data file. Fixes [issue 525](#), [issue 412](#), [issue 516](#), and probably [issue 511](#).
- Coverage.py wouldn't execute `sys.excepthook` when an exception happened in your program. Now it does, thanks to Andrew Hoos. Closes [issue 535](#).
- Branch coverage fixes:
 - Branch coverage could misunderstand a finally clause on a try block that never continued on to the following statement, as described in [issue 493](#). This is now fixed. Thanks to Joe Doherty for the report and Loïc Dachary for the fix.
 - A while loop with a constant condition (`while True`) and a continue statement would be mis-analyzed, as described in [issue 496](#). This is now fixed, thanks to a bug report by Eli Skeggs and a fix by Loïc Dachary.
 - While loops with constant conditions that were never executed could result in a non-zero coverage report. Artem Dayneko reported this in [issue 502](#), and Loïc Dachary provided the fix.
- The HTML report now supports a `--skip-covered` option like the other reporting commands. Thanks, Loïc Dachary for the implementation, closing [issue 433](#).
- Options can now be read from a `tox.ini` file, if any. Like `setup.cfg`, sections are prefixed with "coverage:", so `[run]` options will be read from the `[coverage:run]` section of `tox.ini`. Implements part of [issue 519](#). Thanks, Stephen Finucane.
- Specifying both `--source` and `--include` no longer silently ignores the include setting, instead it fails with a message. Thanks, Nathan Land and Loïc Dachary. Closes [issue 265](#).
- The `Coverage.combine` method has a new parameter, `strict=False`, to support failing if there are no data files to combine.
- When forking subprocesses, the coverage data files would have the same random number appended to the file name. This didn't cause problems, because the file names had the process id also, making collisions (nearly) impossible. But it was disconcerting. This is now fixed.
- The text report now properly sizes headers when skipping some files, fixing [issue 524](#). Thanks, Anthony Sottile and Loïc Dachary.
- Coverage.py can now search `.pex` files for source, just as it can `.zip` and `.egg`. Thanks, Peter Ebdon.
- Data files are now about 15% smaller.
- Improvements in the `[run] debug` setting:

- The “dataio” debug setting now also logs when data files are deleted during combining or erasing.
- A new debug option, “multiproc”, for logging the behavior of `concurrency=multiprocessing`.
- If you used the debug options “config” and “callers” together, you’d get a call stack printed for every line in the multi-line config output. This is now fixed.
- Fixed an unusual bug involving multiple coding declarations affecting code containing code in multi-line strings: [issue 529](#).
- Coverage.py will no longer be misled into thinking that a plain file is a package when interpreting `--source` options. Thanks, Cosimo Lupo.
- If you try to run a non-Python file with coverage.py, you will now get a more useful error message. [Issue 514](#).
- The default pragma regex changed slightly, but this will only matter to you if you are deranged and use mixed-case pragmas.
- Deal properly with non-ASCII file names in an ASCII-only world, [issue 533](#).
- Programs that set Unicode configuration values could cause UnicodeErrors when generating HTML reports. Pytest-cov is one example. This is now fixed.
- Prevented deprecation warnings from configparser that happened in some circumstances, closing [issue 530](#).
- Corrected the name of the `jquery.ba-throttle-debounce.js` library. Thanks, Ben Finney. Closes [issue 505](#).
- Testing against PyPy 5.6 and PyPy3 5.5.
- Switched to pytest from nose for running the coverage.py tests.
- Renamed AUTHORS.txt to CONTRIBUTORS.txt, since there are other ways to contribute than by writing code. Also put the count of contributors into the author string in `setup.py`, though this might be too cute.

5.16.36 Version 4.2 — 2016-07-26

- Since `concurrency=multiprocessing` uses subprocesses, options specified on the coverage.py command line will not be communicated down to them. Only options in the configuration file will apply to the subprocesses. Previously, the options didn’t apply to the subprocesses, but there was no indication. Now it is an error to use `--concurrency=multiprocessing` and other run-affecting options on the command line. This prevents failures like those reported in [issue 495](#).
- Filtering the HTML report is now faster, thanks to Ville Skyttä.

5.16.37 Version 4.2b1 — 2016-07-04

Work from the PyCon 2016 Sprints!

- **BACKWARD INCOMPATIBILITY:** the `coverage combine` command now ignores an existing `.coverage` data file. It used to include that file in its combining. This caused confusing results, and extra `tox “clean”` steps. If you want the old behavior, use the new `coverage combine --append` option.
- The `concurrency` option can now take multiple values, to support programs using multiprocessing and another library such as eventlet. This is only possible in the configuration file, not from the command line. The configuration file is the only way for sub-processes to all run with the same options. Fixes [issue 484](#). Thanks to Josh Williams for prototyping.
- Using a `concurrency` setting of `multiprocessing` now implies `--parallel` so that the main program is measured similarly to the sub-processes.

- When using `automatic subprocess measurement`, running coverage commands would create spurious data files. This is now fixed, thanks to diagnosis and testing by Dan Riti. Closes [issue 492](#).
- A new configuration option, `report:sort`, controls what column of the text report is used to sort the rows. Thanks to Dan Wandschneider, this closes [issue 199](#).
- The HTML report has a more-visible indicator for which column is being sorted. Closes [issue 298](#), thanks to Josh Williams.
- If the HTML report cannot find the source for a file, the message now suggests using the `-i` flag to allow the report to continue. Closes [issue 231](#), thanks, Nathan Land.
- When reports are ignoring errors, there's now a warning if a file cannot be parsed, rather than being silently ignored. Closes [issue 396](#). Thanks, Matthew Boehm.
- A new option for `coverage debug` is available: `coverage debug config` shows the current configuration. Closes [issue 454](#), thanks to Matthew Boehm.
- Running coverage as a module (`python -m coverage`) no longer shows the program name as `__main__`. `py`. Fixes [issue 478](#). Thanks, Scott Belden.
- The `test_helpers` module has been moved into a separate pip-installable package: `unittest-mixins`.

5.16.38 Version 4.1 — 2016-05-21

- The internal attribute `Reporter.file_reporters` was removed in 4.1b3. It should have come has no surprise that there were third-party tools out there using that attribute. It has been restored, but with a deprecation warning.

5.16.39 Version 4.1b3 — 2016-05-10

- When running your program, execution can jump from an `except X:` line to some other line when an exception other than `X` happens. This jump is no longer considered a branch when measuring branch coverage.
- When measuring branch coverage, `yield` statements that were never resumed were incorrectly marked as missing, as reported in [issue 440](#). This is now fixed.
- During branch coverage of single-line callables like lambdas and generator expressions, coverage.py can now distinguish between them never being called, or being called but not completed. Fixes [issue 90](#), [issue 460](#) and [issue 475](#).
- The HTML report now has a map of the file along the rightmost edge of the page, giving an overview of where the missed lines are. Thanks, Dmitry Shishov.
- The HTML report now uses different monospaced fonts, favoring Consolas over Courier. Along the way, [issue 472](#) about not properly handling one-space indents was fixed. The index page also has slightly different styling, to try to make the clickable detail pages more apparent.
- Missing branches reported with `coverage report -m` will now say `->exit` for missed branches to the exit of a function, rather than a negative number. Fixes [issue 469](#).
- `coverage --help` and `coverage --version` now mention which tracer is installed, to help diagnose problems. The docs mention which features need the C extension. ([issue 479](#))
- Officially support PyPy 5.1, which required no changes, just updates to the docs.
- The `Coverage.report` function had two parameters with non-None defaults, which have been changed. `show_missing` used to default to True, but now defaults to None. If you had been calling `Coverage.report` without specifying `show_missing`, you'll need to explicitly set it to True to keep the same behavior. `skip_covered` used to default to False. It is now None, which doesn't change the behavior. This fixes [issue 485](#).

- It's never been possible to pass a namespace module to one of the analysis functions, but now at least we raise a more specific error message, rather than getting confused. ([issue 456](#))
- The `coverage.process_startup` function now returns the `Coverage` instance it creates, as suggested in [issue 481](#).
- Make a small tweak to how we compare threads, to avoid buggy custom comparison code in thread classes. ([issue 245](#))

5.16.40 Version 4.1b2 — 2016-01-23

- Problems with the new branch measurement in 4.1 beta 1 were fixed:
 - Class docstrings were considered executable. Now they no longer are.
 - `yield from` and `await` were considered returns from functions, since they could transfer control to the caller. This produced unhelpful “missing branch” reports in a number of circumstances. Now they no longer are considered returns.
 - In unusual situations, a missing branch to a negative number was reported. This has been fixed, closing [issue 466](#).
- The XML report now produces correct package names for modules found in directories specified with `source=`. Fixes [issue 465](#).
- `coverage report` won't produce trailing whitespace.

5.16.41 Version 4.1b1 — 2016-01-10

- Branch analysis has been rewritten: it used to be based on bytecode, but now uses AST analysis. This has changed a number of things:
 - More code paths are now considered runnable, especially in `try/except` structures. This may mean that `coverage.py` will identify more code paths as uncovered. This could either raise or lower your overall coverage number.
 - Python 3.5's `async` and `await` keywords are properly supported, fixing [issue 434](#).
 - Some long-standing branch coverage bugs were fixed:
 - * [issue 129](#): functions with only a docstring for a body would incorrectly report a missing branch on the `def` line.
 - * [issue 212](#): code in an `except` block could be incorrectly marked as a missing branch.
 - * [issue 146](#): context managers (`with` statements) in a loop or `try` block could confuse the branch measurement, reporting incorrect partial branches.
 - * [issue 422](#): in Python 3.5, an actual partial branch could be marked as complete.
- Pragmas to disable coverage measurement can now be used on decorator lines, and they will apply to the entire function or class being decorated. This implements the feature requested in [issue 131](#).
- Multiprocessing support is now available on Windows. Thanks, Rodrigue Cloutier.
- Files with two encoding declarations are properly supported, fixing [issue 453](#). Thanks, Max Linke.
- Non-ascii characters in regexes in the configuration file worked in 3.7, but stopped working in 4.0. Now they work again, closing [issue 455](#).
- Form-feed characters would prevent accurate determination of the beginning of statements in the rest of the file. This is now fixed, closing [issue 461](#).

5.16.42 Version 4.0.3 — 2015-11-24

- Fixed a mysterious problem that manifested in different ways: sometimes hanging the process ([issue 420](#)), sometimes making database connections fail ([issue 445](#)).
- The XML report now has correct `<source>` elements when using a `--source=` option somewhere besides the current directory. This fixes [issue 439](#). Thanks, Arcadiy Ivanov.
- Fixed an unusual edge case of detecting source encodings, described in [issue 443](#).
- Help messages that mention the command to use now properly use the actual command name, which might be different than “coverage”. Thanks to Ben Finney, this closes [issue 438](#).

5.16.43 Version 4.0.2 — 2015-11-04

- More work on supporting unusually encoded source. Fixed [issue 431](#).
- Files or directories with non-ASCII characters are now handled properly, fixing [issue 432](#).
- Setting a trace function with `sys.settrace` was broken by a change in 4.0.1, as reported in [issue 436](#). This is now fixed.
- Officially support PyPy 4.0, which required no changes, just updates to the docs.

5.16.44 Version 4.0.1 — 2015-10-13

- When combining data files, unreadable files will now generate a warning instead of failing the command. This is more in line with the older coverage.py v3.7.1 behavior, which silently ignored unreadable files. Prompted by [issue 418](#).
- The `--skip-covered` option would skip reporting on 100% covered files, but also skipped them when calculating total coverage. This was wrong, it should only remove lines from the report, not change the final answer. This is now fixed, closing [issue 423](#).
- In 4.0, the data file recorded a summary of the system on which it was run. Combined data files would keep all of those summaries. This could lead to enormous data files consisting of mostly repetitive useless information. That summary is now gone, fixing [issue 415](#). If you want summary information, get in touch, and we'll figure out a better way to do it.
- Test suites that mocked `os.path.exists` would experience strange failures, due to coverage.py using their mock inadvertently. This is now fixed, closing [issue 416](#).
- Importing a `__init__` module explicitly would lead to an error: `AttributeError: 'module' object has no attribute '__path__'`, as reported in [issue 410](#). This is now fixed.
- Code that uses `sys.settrace(sys.gettrace())` used to incur a more than 2x speed penalty. Now there's no penalty at all. Fixes [issue 397](#).
- Pyexpat C code will no longer be recorded as a source file, fixing [issue 419](#).
- The source kit now contains all of the files needed to have a complete source tree, re-fixing [issue 137](#) and closing [issue 281](#).

5.16.45 Version 4.0 — 2015-09-20

No changes from 4.0b3

5.16.46 Version 4.0b3 — 2015-09-07

- Reporting on an unmeasured file would fail with a traceback. This is now fixed, closing [issue 403](#).
- The Jenkins [ShiningPanda](#) plugin looks for an obsolete file name to find the HTML reports to publish, so it was failing under coverage.py 4.0. Now we create that file if we are running under Jenkins, to keep things working smoothly. [issue 404](#).
- Kits used to include tests and docs, but didn't install them anywhere, or provide all of the supporting tools to make them useful. Kits no longer include tests and docs. If you were using them from the older packages, get in touch and help me understand how.

5.16.47 Version 4.0b2 — 2015-08-22

- 4.0b1 broke `--append` creating new data files. This is now fixed, closing [issue 392](#).
- `py.test --cov` can write empty data, then touch files due to `--source`, which made coverage.py mistakenly force the data file to record lines instead of arcs. This would lead to a “Can't combine line data with arc data” error message. This is now fixed, and changed some method names in the CoverageData interface. Fixes [issue 399](#).
- `CoverageData.read_fileobj` and `CoverageData.write_fileobj` replace the `.read` and `.write` methods, and are now properly inverses of each other.
- When using `report --skip-covered`, a message will now be included in the report output indicating how many files were skipped, and if all files are skipped, coverage.py won't accidentally scold you for having no data to report. Thanks, Krystian Kichewko.
- A new conversion utility has been added: `python -m coverage.pickle2json` will convert v3.x pickle data files to v4.x JSON data files. Thanks, Alexander Todorov. Closes [issue 395](#).
- A new version identifier is available, `coverage.version_info`, a plain tuple of values similar to `sys.version_info`.

5.16.48 Version 4.0b1 — 2015-08-02

- Coverage.py is now licensed under the Apache 2.0 license. See NOTICE.txt for details. Closes [issue 313](#).
- The data storage has been completely revamped. The data file is now JSON-based instead of a pickle, closing [issue 236](#). The `CoverageData` class is now a public supported documented API to the data file.
- A new configuration option, `[run] note`, lets you set a note that will be stored in the `runs` section of the data file. You can use this to annotate the data file with any information you like.
- Unrecognized configuration options will now print an error message and stop coverage.py. This should help prevent configuration mistakes from passing silently. Finishes [issue 386](#).
- In parallel mode, `coverage erase` will now delete all of the data files, fixing [issue 262](#).
- Coverage.py now accepts a directory name for `coverage run` and will run a `__main__.py` found there, just like Python will. Fixes [issue 252](#). Thanks, Dmitry Trofimov.
- The XML report now includes a `missing-branches` attribute. Thanks, Steve Peak. This is not a part of the Cobertura DTD, so the XML report no longer references the DTD.

- Missing branches in the HTML report now have a bit more information in the right-hand annotations. Hopefully this will make their meaning clearer.
- All the reporting functions now behave the same if no data had been collected, exiting with a status code of 1. Fixed `fail_under` to be applied even when the report is empty. Thanks, Ionel Cristian Mărieș.
- Plugins are now initialized differently. Instead of looking for a class called `Plugin`, `coverage.py` looks for a function called `coverage_init`.
- A file-tracing plugin can now ask to have built-in Python reporting by returning “*python*” from its `file_reporter()` method.
- Code that was executed with `exec` would be mis-attributed to the file that called it. This is now fixed, closing [issue 380](#).
- The ability to use item access on `Coverage.config` (introduced in 4.0a2) has been changed to a more explicit `Coverage.get_option` and `Coverage.set_option` API.
- The `Coverage.use_cache` method is no longer supported.
- The private method `Coverage._harvest_data` is now called `Coverage.get_data`, and returns the `CoverageData` containing the collected data.
- The project is consistently referred to as “coverage.py” throughout the code and the documentation, closing [issue 275](#).
- Combining data files with an explicit configuration file was broken in 4.0a6, but now works again, closing [issue 385](#).
- `coverage combine` now accepts files as well as directories.
- The speed is back to 3.7.1 levels, after having slowed down due to plugin support, finishing up [issue 387](#).

5.16.49 Version 4.0a6 — 2015-06-21

- Python 3.5b2 and PyPy 2.6.0 are supported.
- The original module-level function interface to `coverage.py` is no longer supported. You must now create a `coverage.Coverage` object, and use methods on it.
- The `coverage combine` command now accepts any number of directories as arguments, and will combine all the data files from those directories. This means you don’t have to copy the files to one directory before combining. Thanks, Christine Lytwynec. Finishes [issue 354](#).
- Branch coverage couldn’t properly handle certain extremely long files. This is now fixed ([issue 359](#)).
- Branch coverage didn’t understand `yield` statements properly. Mickie Betz persisted in pursuing this despite Ned’s pessimism. Fixes [issue 308](#) and [issue 324](#).
- The `COVERAGE_DEBUG` environment variable can be used to set the `[run] debug` configuration option to control what internal operations are logged.
- HTML reports were truncated at formfeed characters. This is now fixed ([issue 360](#)). It’s always fun when the problem is due to a [bug in the Python standard library](#).
- Files with incorrect encoding declaration comments are no longer ignored by the reporting commands, fixing [issue 351](#).
- HTML reports now include a timestamp in the footer, closing [issue 299](#). Thanks, Conrad Ho.
- HTML reports now begrudgingly use double-quotes rather than single quotes, because there are “software engineers” out there writing tools that read HTML and somehow have no idea that single quotes exist. Capitulates to the absurd [issue 361](#). Thanks, Jon Chappell.

- The `coverage annotate` command now handles non-ASCII characters properly, closing [issue 363](#). Thanks, Leonardo Pistone.
- Drive letters on Windows were not normalized correctly, now they are. Thanks, Ionel Cristian Mărieș.
- Plugin support had some bugs fixed, closing [issue 374](#) and [issue 375](#). Thanks, Stefan Behnel.

5.16.50 Version 4.0a5 — 2015-02-16

- Plugin support is now implemented in the C tracer instead of the Python tracer. This greatly improves the speed of tracing projects using plugins.
- Coverage.py now always adds the current directory to `sys.path`, so that plugins can import files in the current directory ([issue 358](#)).
- If the `config_file` argument to the Coverage constructor is specified as `“.coveragerc”`, it is treated as if it were `True`. This means `setup.cfg` is also examined, and a missing file is not considered an error ([issue 357](#)).
- Wildly experimental: support for measuring processes started by the multiprocessing module. To use, set `--concurrency=multiprocessing`, either on the command line or in the `.coveragerc` file ([issue 117](#)). Thanks, Eduardo Schettino. Currently, this does not work on Windows.
- A new warning is possible, if a desired file isn’t measured because it was imported before `coverage.py` was started ([issue 353](#)).
- The `coverage.process_startup` function now will start coverage measurement only once, no matter how many times it is called. This fixes problems due to unusual virtualenv configurations ([issue 340](#)).
- Added 3.5.0a1 to the list of supported CPython versions.

5.16.51 Version 4.0a4 — 2015-01-25

- Plugins can now provide `sys_info` for debugging output.
- Started plugins documentation.
- Prepared to move the docs to [readthedocs.org](#).

5.16.52 Version 4.0a3 — 2015-01-20

- Reports now use file names with extensions. Previously, a report would describe `a/b/c.py` as `“a/b/c”`. Now it is shown as `“a/b/c.py”`. This allows for better support of non-Python files, and also fixed [issue 69](#).
- The XML report now reports each directory as a package again. This was a bad regression, I apologize. This was reported in [issue 235](#), which is now fixed.
- A new configuration option for the XML report: `[xml] package_depth` controls which directories are identified as packages in the report. Directories deeper than this depth are not reported as packages. The default is that all directories are reported as packages. Thanks, Lex Berezhny.
- When looking for the source for a frame, check if the file exists. On Windows, `.pyw` files are no longer recorded as `.py` files. Along the way, this fixed [issue 290](#).
- Empty files are now reported as 100% covered in the XML report, not 0% covered ([issue 345](#)).
- Regexes in the configuration file are now compiled as soon as they are read, to provide error messages earlier ([issue 349](#)).

5.16.53 Version 4.0a2 — 2015-01-14

- Officially support PyPy 2.4, and PyPy3 2.4. Drop support for CPython 3.2 and older versions of PyPy. The code won't work on CPython 3.2. It will probably still work on older versions of PyPy, but I'm not testing against them.
- Plugins!
- The original command line switches (`-x` to run a program, etc) are no longer supported.
- A new option: `coverage report --skip-covered` will reduce the number of files reported by skipping files with 100% coverage. Thanks, Krystian Kichewko. This means that empty `__init__.py` files will be skipped, since they are 100% covered, closing [issue 315](#).
- You can now specify the `--fail-under` option in the `.coveragerc` file as the `[report] fail_under` option. This closes [issue 314](#).
- The `COVERAGE_OPTIONS` environment variable is no longer supported. It was a hack for `--timid` before configuration files were available.
- The HTML report now has filtering. Type text into the Filter box on the index page, and only modules with that text in the name will be shown. Thanks, Danny Allen.
- The textual report and the HTML report used to report partial branches differently for no good reason. Now the text report's "missing branches" column is a "partial branches" column so that both reports show the same numbers. This closes [issue 342](#).
- If you specify a `--rcfile` that cannot be read, you will get an error message. Fixes [issue 343](#).
- The `--debug` switch can now be used on any command.
- You can now programmatically adjust the configuration of `coverage.py` by setting items on `Coverage.config` after construction.
- A module run with `-m` can be used as the argument to `--source`, fixing [issue 328](#). Thanks, Buck Evan.
- The regex for matching exclusion pragmas has been fixed to allow more kinds of whitespace, fixing [issue 334](#).
- Made some PyPy-specific tweaks to improve speed under PyPy. Thanks, Alex Gaynor.
- In some cases, with a source file missing a final newline, `coverage.py` would count statements incorrectly. This is now fixed, closing [issue 293](#).
- The `status.dat` file that HTML reports use to avoid re-creating files that haven't changed is now a JSON file instead of a pickle file. This obviates [issue 287](#) and [issue 237](#).

5.16.54 Version 4.0a1 — 2014-09-27

- Python versions supported are now CPython 2.6, 2.7, 3.2, 3.3, and 3.4, and PyPy 2.2.
- Gevent, eventlet, and greenlet are now supported, closing [issue 149](#). The `concurrency` setting specifies the concurrency library in use. Huge thanks to Peter Portante for initial implementation, and to Joe Jevnik for the final insight that completed the work.
- Options are now also read from a `setup.cfg` file, if any. Sections are prefixed with "coverage:", so the `[run]` options will be read from the `[coverage:run]` section of `setup.cfg`. Finishes [issue 304](#).
- The `report -m` command can now show missing branches when reporting on branch coverage. Thanks, Steve Leonard. Closes [issue 230](#).
- The XML report now contains a `<source>` element, fixing [issue 94](#). Thanks Stan Hu.

- The class defined in the coverage module is now called `Coverage` instead of `coverage`, though the old name still works, for backward compatibility.
- The `fail-under` value is now rounded the same as reported results, preventing paradoxical results, fixing [issue 284](#).
- The XML report will now create the output directory if need be, fixing [issue 285](#). Thanks, Chris Rose.
- HTML reports no longer raise `UnicodeDecodeError` if a Python file has undecodable characters, fixing [issue 303](#) and [issue 331](#).
- The `annotate` command will now annotate all files, not just ones relative to the current directory, fixing [issue 57](#).
- The coverage module no longer causes deprecation warnings on Python 3.4 by importing the `imp` module, fixing [issue 305](#).
- Encoding declarations in source files are only considered if they are truly comments. Thanks, Anthony Sottile.

5.16.55 Version 3.7.1 — 2013-12-13

- Improved the speed of HTML report generation by about 20%.
- Fixed the mechanism for finding OS-installed static files for the HTML report so that it will actually find OS-installed static files.

5.16.56 Version 3.7 — 2013-10-06

- Added the `--debug` switch to `coverage run`. It accepts a list of options indicating the type of internal activity to log to `stderr`.
- Improved the branch coverage facility, fixing [issue 92](#) and [issue 175](#).
- Running code with `coverage run -m` now behaves more like Python does, setting `sys.path` properly, which fixes [issue 207](#) and [issue 242](#).
- Coverage.py can now run `.pyc` files directly, closing [issue 264](#).
- Coverage.py properly supports `.pyw` files, fixing [issue 261](#).
- Omitting files within a tree specified with the `source` option would cause them to be incorrectly marked as unexecuted, as described in [issue 218](#). This is now fixed.
- When specifying paths to alias together during data combining, you can now specify relative paths, fixing [issue 267](#).
- Most file paths can now be specified with username expansion (`~/src`, or `~build/src`, for example), and with environment variable expansion (`build/$BUILDNUM/src`).
- Trying to create an XML report with no files to report on, would cause a `ZeroDivideError`, but no longer does, fixing [issue 250](#).
- When running a threaded program under the Python tracer, coverage.py no longer issues a spurious warning about the trace function changing: “Trace function changed, measurement is likely wrong: None.” This fixes [issue 164](#).
- Static files necessary for HTML reports are found in system-installed places, to ease OS-level packaging of coverage.py. Closes [issue 259](#).
- Source files with encoding declarations, but a blank first line, were not decoded properly. Now they are. Thanks, Roger Hu.
- The source kit now includes the `__main__.py` file in the root coverage directory, fixing [issue 255](#).

5.16.57 Version 3.6 — 2013-01-05

- Added a page to the docs about troublesome situations, closing [issue 226](#), and added some info to the TODO file, closing [issue 227](#).

5.16.58 Version 3.6b3 — 2012-12-29

- Beta 2 broke the nose plugin. It's fixed again, closing [issue 224](#).

5.16.59 Version 3.6b2 — 2012-12-23

- Coverage.py runs on Python 2.3 and 2.4 again. It was broken in 3.6b1.
- The C extension is optionally compiled using a different more widely-used technique, taking another stab at fixing [issue 80](#) once and for all.
- Combining data files would create entries for phantom files if used with `source` and path aliases. It no longer does.
- `debug sys` now shows the configuration file path that was read.
- If an oddly-behaved package claims that code came from an empty-string file name, coverage.py no longer associates it with the directory name, fixing [issue 221](#).

5.16.60 Version 3.6b1 — 2012-11-28

- Wildcards in `include=` and `omit=` arguments were not handled properly in reporting functions, though they were when running. Now they are handled uniformly, closing [issue 143](#) and [issue 163](#). **NOTE:** it is possible that your configurations may now be incorrect. If you use `include` or `omit` during reporting, whether on the command line, through the API, or in a configuration file, please check carefully that you were not relying on the old broken behavior.
- The **report**, **html**, and **xml** commands now accept a `--fail-under` switch that indicates in the exit status whether the coverage percentage was less than a particular value. Closes [issue 139](#).
- The reporting functions `coverage.report()`, `coverage.html_report()`, and `coverage.xml_report()` now all return a float, the total percentage covered measurement.
- The HTML report's title can now be set in the configuration file, with the `--title` switch on the command line, or via the API.
- Configuration files now support substitution of environment variables, using syntax like `${WORD}`. Closes [issue 97](#).
- Embarrassingly, the `[xml] output=` setting in the `.coveragerc` file simply didn't work. Now it does.
- The XML report now consistently uses file names for the file name attribute, rather than sometimes using module names. Fixes [issue 67](#). Thanks, Marcus Cobden.
- Coverage percentage metrics are now computed slightly differently under branch coverage. This means that completely unexecuted files will now correctly have 0% coverage, fixing [issue 156](#). This also means that your total coverage numbers will generally now be lower if you are measuring branch coverage.
- When installing, now in addition to creating a "coverage" command, two new aliases are also installed. A "coverage2" or "coverage3" command will be created, depending on whether you are installing in Python 2.x or 3.x. A "coverage-X.Y" command will also be created corresponding to your specific version of Python. Closes [issue 111](#).

- The coverage.py installer no longer tries to bootstrap setuptools or Distribute. You must have one of them installed first, as [issue 202](#) recommended.
- The coverage.py kit now includes docs (closing [issue 137](#)) and tests.
- On Windows, files are now reported in their correct case, fixing [issue 89](#) and [issue 203](#).
- If a file is missing during reporting, the path shown in the error message is now correct, rather than an incorrect path in the current directory. Fixes [issue 60](#).
- Running an HTML report in Python 3 in the same directory as an old Python 2 HTML report would fail with a UnicodeDecodeError. This issue ([issue 193](#)) is now fixed.
- Fixed yet another error trying to parse non-Python files as Python, this time an IndentationError, closing [issue 82](#) for the fourth time. . .
- If *coverage xml* fails because there is no data to report, it used to create a zero-length XML file. Now it doesn't, fixing [issue 210](#).
- Python files now work with the `--source` option, fixing [issue 100](#).
- Running coverage.py under a debugger is unlikely to work, but it shouldn't fail with "TypeError: 'NoneType' object is not iterable". Fixes [issue 201](#).
- On some Linux distributions, when installed with the OS package manager, coverage.py would report its own code as part of the results. Now it won't, fixing [issue 214](#), though this will take some time to be repackaged by the operating systems.
- Docstrings for the legacy singleton methods are more helpful. Thanks Marius Gedminas. Closes [issue 205](#).
- The pydoc tool can now show documentation for the class *coverage.coverage*. Closes [issue 206](#).
- Added a page to the docs about contributing to coverage.py, closing [issue 171](#).
- When coverage.py ended unsuccessfully, it may have reported odd errors like 'NoneType' object has no attribute 'isabs'. It no longer does, so kiss [issue 153](#) goodbye.

5.16.61 Version 3.5.3 — 2012-09-29

- Line numbers in the HTML report line up better with the source lines, fixing [issue 197](#), thanks Marius Gedminas.
- When specifying a directory as the `source=` option, the directory itself no longer needs to have a `__init__.py` file, though its sub-directories do, to be considered as source files.
- Files encoded as UTF-8 with a BOM are now properly handled, fixing [issue 179](#). Thanks, Pablo Carballo.
- Fixed more cases of non-Python files being reported as Python source, and then not being able to parse them as Python. Closes [issue 82](#) (again). Thanks, Julian Berman.
- Fixed memory leaks under Python 3, thanks, Brett Cannon. Closes [issue 147](#).
- Optimized .pyo files may not have been handled correctly, [issue 195](#). Thanks, Marius Gedminas.
- Certain unusually named file paths could have been mangled during reporting, [issue 194](#). Thanks, Marius Gedminas.
- Try to do a better job of the impossible task of detecting when we can't build the C extension, fixing [issue 183](#).
- Testing is now done with `tox`, thanks, Marc Abramowitz.

5.16.62 Version 3.5.2 — 2012-05-04

No changes since 3.5.2.b1

5.16.63 Version 3.5.2b1 — 2012-04-29

- The HTML report has slightly tweaked controls: the buttons at the top of the page are color-coded to the source lines they affect.
- Custom CSS can be applied to the HTML report by specifying a CSS file as the `extra_css` configuration value in the `[html]` section.
- Source files with custom encodings declared in a comment at the top are now properly handled during reporting on Python 2. Python 3 always handled them properly. This fixes [issue 157](#).
- Backup files left behind by editors are no longer collected by the `source=` option, fixing [issue 168](#).
- If a file doesn't parse properly as Python, we don't report it as an error if the file name seems like maybe it wasn't meant to be Python. This is a pragmatic fix for [issue 82](#).
- The `-m` switch on `coverage report`, which includes missing line numbers in the summary report, can now be specified as `show_missing` in the config file. Closes [issue 173](#).
- When running a module with `coverage run -m <modulename>`, certain details of the execution environment weren't the same as for `python -m <modulename>`. This had the unfortunate side-effect of making `coverage run -m unittest discover` not work if you had tests in a directory named "test". This fixes [issue 155](#) and [issue 142](#).
- Now the exit status of your product code is properly used as the process status when running `python -m coverage run . . .`. Thanks, JT Olds.
- When installing into pypy, we no longer attempt (and fail) to compile the C tracer function, closing [issue 166](#).

5.16.64 Version 3.5.1 — 2011-09-23

- The `[paths]` feature unfortunately didn't work in real world situations where you wanted to, you know, report on the combined data. Now all paths stored in the combined file are canonicalized properly.

5.16.65 Version 3.5.1b1 — 2011-08-28

- When combining data files from parallel runs, you can now instruct coverage.py about which directories are equivalent on different machines. A `[paths]` section in the configuration file lists paths that are to be considered equivalent. Finishes [issue 17](#).
- for-else constructs are understood better, and don't cause erroneous partial branch warnings. Fixes [issue 122](#).
- Branch coverage for `with` statements is improved, fixing [issue 128](#).
- The number of partial branches reported on the HTML summary page was different than the number reported on the individual file pages. This is now fixed.
- An explicit `include` directive to measure files in the Python installation wouldn't work because of the standard library exclusion. Now the `include` directive takes precedence, and the files will be measured. Fixes [issue 138](#).
- The HTML report now handles Unicode characters in Python source files properly. This fixes [issue 124](#) and [issue 144](#). Thanks, Devin Jeanpierre.

- In order to help the core developers measure the test coverage of the standard library, Brandon Rhodes devised an aggressive hack to trick Python into running some coverage.py code before anything else in the process. See the coverage/fullcoverage directory if you are interested.

5.16.66 Version 3.5 — 2011-06-29

- The HTML report hotkeys now behave slightly differently when the current chunk isn't visible at all: a chunk on the screen will be selected, instead of the old behavior of jumping to the literal next chunk. The hotkeys now work in Google Chrome. Thanks, Guido van Rossum.

5.16.67 Version 3.5b1 — 2011-06-05

- The HTML report now has hotkeys. Try `n`, `s`, `m`, `x`, `b`, `p`, and `c` on the overview page to change the column sorting. On a file page, `r`, `m`, `x`, and `p` toggle the run, missing, excluded, and partial line markings. You can navigate the highlighted sections of code by using the `j` and `k` keys for next and previous. The `1` (one) key jumps to the first highlighted section in the file, and `0` (zero) scrolls to the top of the file.
- The `--omit` and `--include` switches now interpret their values more usefully. If the value starts with a wildcard character, it is used as-is. If it does not, it is interpreted relative to the current directory. Closes [issue 121](#).
- Partial branch warnings can now be pragma'd away. The configuration option `partial_branches` is a list of regular expressions. Lines matching any of those expressions will never be marked as a partial branch. In addition, there's a built-in list of regular expressions marking statements which should never be marked as partial. This list includes `while True:`, `while 1:`, `if 1:`, and `if 0:`.
- The `coverage()` constructor accepts single strings for the `omit=` and `include=` arguments, adapting to a common error in programmatic use.
- Modules can now be run directly using `coverage run -m modulename`, to mirror Python's `-m` flag. Closes [issue 95](#), thanks, Brandon Rhodes.
- `coverage run` didn't emulate Python accurately in one small detail: the current directory inserted into `sys.path` was relative rather than absolute. This is now fixed.
- HTML reporting is now incremental: a record is kept of the data that produced the HTML reports, and only files whose data has changed will be generated. This should make most HTML reporting faster.
- Pathological code execution could disable the trace function behind our backs, leading to incorrect code measurement. Now if this happens, coverage.py will issue a warning, at least alerting you to the problem. Closes [issue 93](#). Thanks to Marius Gedminas for the idea.
- The C-based trace function now behaves properly when saved and restored with `sys.gettrace()` and `sys.settrace()`. This fixes [issue 125](#) and [issue 123](#). Thanks, Devin Jeanpierre.
- Source files are now opened with Python 3.2's `tokenize.open()` where possible, to get the best handling of Python source files with encodings. Closes [issue 107](#), thanks, Brett Cannon.
- Syntax errors in supposed Python files can now be ignored during reporting with the `-i` switch just like other source errors. Closes [issue 115](#).
- Installation from source now succeeds on machines without a C compiler, closing [issue 80](#).
- Coverage.py can now be run directly from a working tree by specifying the directory name to python: `python coverage_py_working_dir run ...`. Thanks, Brett Cannon.
- A little bit of Jython support: `coverage run` can now measure Jython execution by adapting when `$py.class` files are traced. Thanks, Adi Roiban. Jython still doesn't provide the Python libraries needed to make coverage reporting work, unfortunately.

- Internally, files are now closed explicitly, fixing [issue 104](#). Thanks, Brett Cannon.

5.16.68 Version 3.4 — 2010-09-19

- The XML report is now sorted by package name, fixing [issue 88](#).
- Programs that exited with `sys.exit()` with no argument weren't handled properly, producing a `coverage.py` stack trace. That is now fixed.

5.16.69 Version 3.4b2 — 2010-09-06

- Completely unexecuted files can now be included in coverage results, reported as 0% covered. This only happens if the `--source` option is specified, since `coverage.py` needs guidance about where to look for source files.
- The XML report output now properly includes a percentage for branch coverage, fixing [issue 65](#) and [issue 81](#).
- Coverage percentages are now displayed uniformly across reporting methods. Previously, different reports could round percentages differently. Also, percentages are only reported as 0% or 100% if they are truly 0 or 100, and are rounded otherwise. Fixes [issue 41](#) and [issue 70](#).
- The precision of reported coverage percentages can be set with the `[report] precision` config file setting. Completes [issue 16](#).
- Threads derived from `threading.Thread` with an overridden `run` method would report no coverage for the `run` method. This is now fixed, closing [issue 85](#).

5.16.70 Version 3.4b1 — 2010-08-21

- BACKWARD INCOMPATIBILITY: the `--omit` and `--include` switches now take file patterns rather than file prefixes, closing [issue 34](#) and [issue 36](#).
- BACKWARD INCOMPATIBILITY: the `omit_prefixes` argument is gone throughout `coverage.py`, replaced with `omit`, a list of file name patterns suitable for `fnmatch`. A parallel argument `include` controls what files are included.
- The `run` command now has a `--source` switch, a list of directories or module names. If provided, `coverage.py` will only measure execution in those source files.
- Various warnings are printed to `stderr` for problems encountered during data measurement: if a `--source` module has no Python source to measure, or is never encountered at all, or if no data is collected.
- The reporting commands (`report`, `annotate`, `html`, and `xml`) now have an `--include` switch to restrict reporting to modules matching those file patterns, similar to the existing `--omit` switch. Thanks, Zooko.
- The `run` command now supports `--include` and `--omit` to control what modules it measures. This can speed execution and reduce the amount of data during reporting. Thanks Zooko.
- Since `coverage.py` 3.1, using the Python trace function has been slower than it needs to be. A cache of tracing decisions was broken, but has now been fixed.
- Python 2.7 and 3.2 have introduced new opcodes that are now supported.
- Python files with no statements, for example, empty `__init__.py` files, are now reported as having zero statements instead of one. Fixes [issue 1](#).
- Reports now have a column of missed line counts rather than executed line counts, since developers should focus on reducing the missed lines to zero, rather than increasing the executed lines to varying targets. Once suggested, this seemed blindingly obvious.

- Line numbers in HTML source pages are clickable, linking directly to that line, which is highlighted on arrival. Added a link back to the index page at the bottom of each HTML page.
- Programs that call `os.fork` will properly collect data from both the child and parent processes. Use `coverage run -p` to get two data files that can be combined with `coverage combine`. Fixes [issue 56](#).
- Coverage.py is now runnable as a module: `python -m coverage`. Thanks, Brett Cannon.
- When measuring code running in a virtualenv, most of the system library was being measured when it shouldn't have been. This is now fixed.
- Doctest text files are no longer recorded in the coverage data, since they can't be reported anyway. Fixes [issue 52](#) and [issue 61](#).
- Jinja HTML templates compile into Python code using the HTML file name, which confused coverage.py. Now these files are no longer traced, fixing [issue 82](#).
- Source files can have more than one dot in them (`foo.test.py`), and will be treated properly while reporting. Fixes [issue 46](#).
- Source files with DOS line endings are now properly tokenized for syntax coloring on non-DOS machines. Fixes [issue 53](#).
- Unusual code structure that confused exits from methods with exits from classes is now properly analyzed. See [issue 62](#).
- Asking for an HTML report with no files now shows a nice error message rather than a cryptic failure ('int' object is unsubscriptable). Fixes [issue 59](#).

5.16.71 Version 3.3.1 — 2010-03-06

- Using `parallel=True` in `.coveragerc` file prevented reporting, but now does not, fixing [issue 49](#).
- When running your code with “coverage run”, if you call `sys.exit()`, coverage.py will exit with that status code, fixing [issue 50](#).

5.16.72 Version 3.3 — 2010-02-24

- Settings are now read from a `.coveragerc` file. A specific file can be specified on the command line with `-rc-file=FILE`. The name of the file can be programmatically set with the `config_file` argument to the `coverage()` constructor, or reading a config file can be disabled with `config_file=False`.
- Fixed a problem with nested loops having their branch possibilities mischaracterized: [issue 39](#).
- Added `coverage.process_start` to enable coverage measurement when Python starts.
- Parallel data file names now have a random number appended to them in addition to the machine name and process id.
- Parallel data files combined with “coverage combine” are deleted after they're combined, to clean up unneeded files. Fixes [issue 40](#).
- Exceptions thrown from product code run with “coverage run” are now displayed without internal coverage.py frames, so the output is the same as when the code is run without coverage.py.
- The `data_suffix` argument to the coverage constructor is now appended with an added dot rather than simply appended, so that `.coveragerc` files will not be confused for data files.
- Python source files that don't end with a newline can now be executed, fixing [issue 47](#).

- Added an AUTHORS.txt file.

5.16.73 Version 3.2 — 2009-12-05

- Added a `--version` option on the command line.

5.16.74 Version 3.2b4 — 2009-12-01

- Branch coverage improvements:
 - The XML report now includes branch information.
- Click-to-sort HTML report columns are now persisted in a cookie. Viewing a report will sort it first the way you last had a coverage report sorted. Thanks, [Chris Adams](#).
- On Python 3.x, `setuptools` has been replaced by `Distribute`.

5.16.75 Version 3.2b3 — 2009-11-23

- Fixed a memory leak in the C tracer that was introduced in 3.2b1.
- Branch coverage improvements:
 - Branches to excluded code are ignored.
- The table of contents in the HTML report is now sortable: click the headers on any column. Thanks, [Chris Adams](#).

5.16.76 Version 3.2b2 — 2009-11-19

- Branch coverage improvements:
 - Classes are no longer incorrectly marked as branches: [issue 32](#).
 - “except” clauses with types are no longer incorrectly marked as branches: [issue 35](#).
- Fixed some problems syntax coloring sources with line continuations and source with tabs: [issue 30](#) and [issue 31](#).
- The `-omit` option now works much better than before, fixing [issue 14](#) and [issue 33](#). Thanks, Danek Duvall.

5.16.77 Version 3.2b1 — 2009-11-10

- Branch coverage!
- XML reporting has file paths that let Cobertura find the source code.
- The tracer code has changed, it’s a few percent faster.
- Some exceptions reported by the command line interface have been cleaned up so that tracebacks inside `coverage.py` aren’t shown. Fixes [issue 23](#).

5.16.78 Version 3.1 — 2009-10-04

- Source code can now be read from eggs. Thanks, Ross Lawley. Fixes [issue 25](#).

5.16.79 Version 3.1b1 — 2009-09-27

- Python 3.1 is now supported.
- Coverage.py has a new command line syntax with sub-commands. This expands the possibilities for adding features and options in the future. The old syntax is still supported. Try “coverage help” to see the new commands. Thanks to Ben Finney for early help.
- Added an experimental “coverage xml” command for producing coverage reports in a Cobertura-compatible XML format. Thanks, Bill Hart.
- Added the `-timid` option to enable a simpler slower trace function that works for DecoratorTools projects, including TurboGears. Fixed [issue 12](#) and [issue 13](#).
- HTML reports show modules from other directories. Fixed [issue 11](#).
- HTML reports now display syntax-colored Python source.
- Programs that change directory will still write `.coverage` files in the directory where execution started. Fixed [issue 24](#).
- Added a “coverage debug” command for getting diagnostic information about the coverage.py installation.

5.16.80 Version 3.0.1 — 2009-07-07

- Removed the recursion limit in the tracer function. Previously, code that ran more than 500 frames deep would crash. Fixed [issue 9](#).
- Fixed a bizarre problem involving pyexpat, whereby lines following XML parser invocations could be overlooked. Fixed [issue 10](#).
- On Python 2.3, coverage.py could mis-measure code with exceptions being raised. This is now fixed.
- The coverage.py code itself will now not be measured by coverage.py, and no coverage.py modules will be mentioned in the nose `-with-cover` plug-in. Fixed [issue 8](#).
- When running source files, coverage.py now opens them in universal newline mode just like Python does. This lets it run Windows files on Mac, for example.

5.16.81 Version 3.0 — 2009-06-13

- Fixed the way the Python library was ignored. Too much code was being excluded the old way.
- Tabs are now properly converted in HTML reports. Previously indentation was lost. Fixed [issue 6](#).
- Nested modules now get a proper `flat_rootname`. Thanks, Christian Heimes.

5.16.82 Version 3.0b3 — 2009-05-16

- Added parameters to `coverage.__init__` for options that had been set on the coverage object itself.
- Added `clear_exclude()` and `get_exclude_list()` methods for programmatic manipulation of the exclude regexes.
- Added `coverage.load()` to read previously-saved data from the data file.
- Improved the finding of code files. For example, `.pyc` files that have been installed after compiling are now located correctly. Thanks, Detlev Offenbach.
- When using the object API (that is, constructing a `coverage()` object), data is no longer saved automatically on process exit. You can re-enable it with the `auto_data=True` parameter on the `coverage()` constructor. The module-level interface still uses automatic saving.

5.16.83 Version 3.0b — 2009-04-30

HTML reporting, and continued refactoring.

- HTML reports and annotation of source files: use the new `-b` (browser) switch. Thanks to George Song for code, inspiration and guidance.
- Code in the Python standard library is not measured by default. If you need to measure standard library code, use the `-L` command-line switch during execution, or the `cover_pylib=True` argument to the `coverage()` constructor.
- Source annotation into a directory (`-a -d`) behaves differently. The annotated files are named with their hierarchy flattened so that same-named files from different directories no longer collide. Also, only files in the current tree are included.
- `coverage.annotate_file` is no longer available.
- Programs executed with `-x` now behave more as they should, for example, `__file__` has the correct value.
- `.coverage` data files have a new pickle-based format designed for better extensibility.
- Removed the undocumented `cache_file` argument to `coverage.usecache()`.

5.16.84 Version 3.0b1 — 2009-03-07

Major overhaul.

- `Coverage.py` is now a package rather than a module. Functionality has been split into classes.
- The trace function is implemented in C for speed. `Coverage.py` runs are now much faster. Thanks to David Christian for productive micro-sprints and other encouragement.
- Executable lines are identified by reading the line number tables in the compiled code, removing a great deal of complicated analysis code.
- Precisely which lines are considered executable has changed in some cases. Therefore, your coverage stats may also change slightly.
- The singleton coverage object is only created if the module-level functions are used. This maintains the old interface while allowing better programmatic use of `coverage.py`.
- The minimum supported Python version is 2.3.

5.16.85 Version 2.85 — 2008-09-14

- Add support for finding source files in eggs. Don't check for morf's being instances of ModuleType, instead use duck typing so that pseudo-modules can participate. Thanks, Imri Goldberg.
- Use os.realpath as part of the fixing of file names so that symlinks won't confuse things. Thanks, Patrick Mezard.

5.16.86 Version 2.80 — 2008-05-25

- Open files in rU mode to avoid line ending craziness. Thanks, Edward Loper.

5.16.87 Version 2.78 — 2007-09-30

- Don't try to predict whether a file is Python source based on the extension. Extension-less files are often Python scripts. Instead, simply parse the file and catch the syntax errors. Hat tip to Ben Finney.

5.16.88 Version 2.77 — 2007-07-29

- Better packaging.

5.16.89 Version 2.76 — 2007-07-23

- Now Python 2.5 is *really* fully supported: the body of the new with statement is counted as executable.

5.16.90 Version 2.75 — 2007-07-22

- Python 2.5 now fully supported. The method of dealing with multi-line statements is now less sensitive to the exact line that Python reports during execution. Pass statements are handled specially so that their disappearance during execution won't throw off the measurement.

5.16.91 Version 2.7 — 2007-07-21

- “#pragma: nocover” is excluded by default.
- Properly ignore docstrings and other constant expressions that appear in the middle of a function, a problem reported by Tim Leslie.
- coverage.erase() shouldn't clobber the exclude regex. Change how parallel mode is invoked, and fix erase() so that it erases the cache when called programmatically.
- In reports, ignore code executed from strings, since we can't do anything useful with it anyway.
- Better file handling on Linux, thanks Guillaume Chazarain.
- Better shell support on Windows, thanks Noel O'Boyle.
- Python 2.2 support maintained, thanks Catherine Proulx.
- Minor changes to avoid lint warnings.

5.16.92 Version 2.6 — 2006-08-23

- Applied Joseph Tate's patch for function decorators.
- Applied Sigve Tjora and Mark van der Wal's fixes for argument handling.
- Applied Geoff Bache's parallel mode patch.
- Refactorings to improve testability. Fixes to command-line logic for parallel mode and collect.

5.16.93 Version 2.5 — 2005-12-04

- Call `threading.settrace` so that all threads are measured. Thanks Martin Fuzzey.
- Add a file argument to report so that reports can be captured to a different destination.
- Coverage.py can now measure itself.
- Adapted Greg Rogers' patch for using relative file names, and sorting and omitting files to report on.

5.16.94 Version 2.2 — 2004-12-31

- Allow for keyword arguments in the module global functions. Thanks, Allen.

5.16.95 Version 2.1 — 2004-12-14

- Return 'analysis' to its original behavior and add 'analysis2'. Add a global for 'annotate', and factor it, adding 'annotate_file'.

5.16.96 Version 2.0 — 2004-12-12

Significant code changes.

- Finding executable statements has been rewritten so that docstrings and other quirks of Python execution aren't mistakenly identified as missing lines.
- Lines can be excluded from consideration, even entire suites of lines.
- The file system cache of covered lines can be disabled programmatically.
- Modernized the code.

5.16.97 Earlier History

2001-12-04 GDR Created.

2001-12-06 GDR Added command-line interface and source code annotation.

2001-12-09 GDR Moved design and interface to separate documents.

2001-12-10 GDR Open cache file as binary on Windows. Allow simultaneous -e and -x, or -a and -r.

2001-12-12 GDR Added command-line help. Cache analysis so that it only needs to be done once when you specify -a and -r.

2001-12-13 GDR Improved speed while recording. Portable between Python 1.5.2 and 2.1.1.

2002-01-03 GDR Module-level functions work correctly.

2002-01-07 GDR Update `sys.path` when running a file with the `-x` option, so that it matches the value the program would get if it were run on its own.

5.17 Sleepy Snake

Coverage.py's mascot is Sleepy Snake, drawn by Ben Batchelder. Ben's art can be found on [Instagram](#) and at artofbatch.com. Some details of Sleepy's creation are on [Ned's blog](#).
